Wealth Inequality, Class and Caste in India, 1961-2012

Nitin Kumar Bharti

November 20, 2018

Abstract

I combine data from wealth surveys (NSS-AIDIS) and millionaire lists to produce wealth inequality series for India over the 1961-2012 period. I find a strong rise in wealth concentration in recent decades, in line with recent research using income data. E.g. the top 10% wealth share rose from 45% in year 1981 to 63% in 2012, while the top 1% share rose from 12.5% to 31%. Next, I gather information from censuses and surveys (NSS AIDIS and IHDS) in order to explore the changing relationship between class and caste in India and the mechanisms behind rising inequality.

ACKNOWLEDGEMENT

I would like to thank my supervisor Professor Thomas Piketty for being very supportive and open to ideas. He was a constant source of motivation for whole year. Next I would like to thank Professor Abhijit Banerjee for agreeing to be referee. His suggestions were very useful, some of which I was able to incorporate. I would like to thank Lucas Chancel for helping me at crucial junctures by gaining access to datasets without which this data intensive thesis would not have been possible. I extend many thanks to Thomas Blanchet for helping me in technical parts of estimation. I thank Professor Pulak Ghosh for the important datasets which will certainly have a bigger role in my future research.

I thank a lot to Michelle Cherian, Kentaro Asai and Matthias Endres for their help in proof reading my initial drafts of this thesis which played big role in finishing this report on time. Also I thank all my friends and family members for their moral support.

1 Introduction

Economic Inequality has become a major issue in the world. With more and more research in the area using different datasets, the gloomy picture of an extremely unequal society is becoming explicit, across the world. Almost all the countries have an increasing graph of income and wealth inequality during the recent few decades. It will be too optimistic to shrug it off as a co-incident. Certainly there are some common factors around the world driving the level of haves and have-nots scenario in society. In this context it is very important to understand different phenomena which could potentially be the reason behind this. It is further interesting to look at the macro picture to understand why different countries, despite being in different development phases, all face an increasing inequality trend.

In the context of global economic inequality, I present the case of wealth inequality in India. I keep the domestic lens of caste active, to not miss the social inequality which might be propelling the uneven distribution of prosperity. I further divide my work here into two sub-topics. First is preparing the long term evolution of wealth inequality series for India. One of the challenges I faced, as any other researcher generally encounters, is the availability of data. A data-driven research carries more weight due to obvious reasons. Fortunately India has a long tradition of wealth surveys. Since 1951, every ten years, all-India surveys are conducted to know the wealth and debt situation in India. These surveys encompass different physical and financial form of assets. There are some concerns over the quality of data and inter-year comparability- which I have tried to overcome in this paper.

India is a very peculiar country with a complex and regressive caste system. In the study of wealth inequality one can't ignore this societal peculiarity which is historically older than wealth inequality. Thus, the second sub-topic is understanding economic inequality within the framework of caste. This paper is limited to presenting some simple ranking orders of average wealth and consumption, representing inequality by deciles within the caste-based framework (i.e. segregation of castes based on wealth, with higher castes concentrated more in top wealth deciles and lower castes concentrated more in lower deciles). Some may wonder if caste has any relevance today. Unfortunately past unequal distribution of wealth along caste lines has never been corrected. A simple depiction is the land distribution in India. Land forms a major part of wealth in India (Rural India- 65% and Urban India 45%). In the past land distribution was entirely based on caste where the upper-castes of society possessed almost all of the land and lower castes predominantly formed the working class. Colonial period concretized the possessions of land by distributing land titles and land ownership. Indeed, post independence India adopted land reforms aiming for the distribution of land ownership to the real farmers who were mainly from the lower castes. However, even going by the reports of the government this measure has met with partial success and the distribution did not go well beyond certain ranks of the castes. Early adoption of an egalitarian meritocratic system was accompanied by a support system in the form of positive affirmation (reservation/quotas) for the lower castes. The data shows that the situation of every caste has improved over time, but there is no convergence between upper and lower castes. The rate of growth of forward/upper castes in terms of acquiring wealth or consumption is higher than the lower castes. Provided there are positive affirmation policies, one will expect the opposite. It hints towards the harsh reality of ongoing caste-based discrimination in the society.

The paper is structured as follows. Chapter 2 connects this work to the existing literature on wealth inequality. Chapter 3 outlines the various data sets used for the analysis. Chapter 4 presents the evolution of demographics of different social groups of India since 1901. Chapter 5 presents the evolution of wealth distribution in India since 1961.

2 Literature

This paper produces long term wealth inequality series of India using survey data and correcting the top wealth distribution using the Forbes millionaires data. It complements the income inequality series produced by Banerjee (2005) and Chancel and Piketty (2017) on India. The basic approach is similar in terms of utilizing all the available resources to estimate the top wealth and consumption shares. There can be mainly 5 ways to estimate the distribution of wealth as outlined in Alvaredo, Atkinson, and Morelli (2016). First are Household Surveys of personal wealth. Second, the administrative data on individual estates at death. Kumar (2016) uses inheritance tax returns with mortality tables data with an estate multiplier technique to produce top .01% wealth share during 1961-85. Inheritance tax was active during 1953-85. This shows the limitation of this data to study recent wealth inequality. Third is the administrative data on wealth of the living derived from annual wealth taxes. Wealth tax prevailed in India during 1957-2016. The productive assets like shares, mutual funds and securities were exempted from wealth tax. Low collection of taxes and higher costs was one of the reason for its abolition.¹ Fourth is the administrative data on investment income, capitalized to get estimates of underlying wealth. Fifth is the list of rich individuals produced by different magazines like, Forbes Billionaire's list. This paper uses Forbes to correct the top share and uses Business Standard millionaire

¹Improving ease of doing business, simplifying the tax rules etc. were some other reasons for its abolition.

list for robustness check.

Household surveys are useful to provide information for the bulk of the population, but suffer from the limitation of not capturing the complete top distribution- either due to non-responses, under-reporting or worse exclusion of the rich (Deaton, 2005; Jayadev, Motiram, and Vakulabharanam, 2007). To emphasize on the issue, I found the combined wealth of top 46 Forbes millionaires in 2012 is 2.5% of the total wealth from nationally representative wealth surveys. Hence I utilize the available Forbes list to correct the top series. In terms of methodology I use the advanced version of standard Pareto interpolation namely Generalized Pareto Interpolation techniques which has been developed in Blanchet, Fournier, and Piketty (2017) and has been used in Piketty, Yang, and Zucman (2017). I contribute in producing the wealth inequality series since 1960's. The combined income-consumption-wealth series on Indian inequality will help in analysing the economic inequality from the three prime economic indicators.

The income share of top 10% population shows an increasing trend since 1980 to reach 55% in 2013. Comparing this to wealth share, I find the top 10% share increasing from 45% in 1981 to 58% (pre-correction) and 62% (post-correction) in 2012.

This paper supplements the existing literature Anand and Thampi (2016), Jayadev, Motiram, and Vakulabharanam (2007), and Zacharias and Vakulabharanam (2011) on wealth inequality in India and in other developing countries in general. The methodology adopted here is new and I compare the results from different methodologies in detail later. The second important point of demarcation is the comprehensive approach undertaken here by visualising wealth inequality not only from economic point of view, but also from social point of view. Gender, Caste and Place of residence are some other dimensions along which inequality has been scrutinized. The main motivation for this comprehensive approach is the peculiar form of Indian inequality where social and economic inequality are weaved together with the thread of caste.

Through this paper, I also add to the existing literature on inequality studies making caste as central social stratification of the society. Deshpande (2001) argued to make caste as an essential ingredient in the study of stratification patterns in India's population and later works Borooah (2005), Thorat (2002), and Zacharias and Vakulabharanam (2011) have highlighted the economic differences among castes which exactly matches with the caste hierarchy present in the society. One extension is through an attempt to disentangle the heterogeneous group of Forward caste² into finer categories, Brahmins, Rajputs, Bania and so on. Lack of any caste census in 1931-2010 and as well as lack of caste information from SECC 2011 (Socio-Economic Caste Census) is a big hindrance to any study along caste lines. It will surprise many that there is no concrete population figure of Other Backward Castes (OBC) in India. It is very recently that national representative surveys have started gathering information on castes- which helps in estimating their respective population. I initiated the process of cleaning, sorting and most importantly categorizing the castes. This is a gigantic effort as there are thousands of castes in Indian society with almost no documentation from recent times. I provide basic demographic and socio-economic characteristics for few well known castes. Lack of any prior attempt is an issue to compare the estimated numbers. One robustness check is to compare the estimated population from two completely different surveys (conducted by different organizations). I intend to carry out this task, as it has huge potential to analyse the population at finer level. The big social groups - SC, ST, OBC, FC are quite heterogeneous, as detailed later, and hence a finer level analysis will help in policy recommendation on reservations (positive affirmative actions) in India.

This paper also contributes towards the literature dealing with the measure of inequality and polarization in societies- by empirically utilizing the theoretical concepts of representational inequality, sequence inequality and group inequality developed in Jayadev and Reddy (2011) on Indian wealth data. Representational Inequality measures a degree of "segregation" of between different social groups along any attribute space.³ Sequence Inequality measures the degree of "clustering" based on hierarchy among social groups. Group Inequality measures the portion of between inequality in the total inequality in a society. I perform Representational Inequality and Sequential Inequality analysis and find the existence of both which has been termed as ordinal polarisation. The population share of all the perceived lower caste groups (SC, ST and OBC) in top decile of wealth and consumption is lower than their overall population share. The situation has deteriorated over the last 40 years. Further a high level of within inequality is found in terms of wealth and consumption which has brief mention in Borooah (2005) also.

²In this paper, I use Forward Caste to denote the Hindu religion population who do not fall under Scheduled Caste (SC), Scheduled Tribe (ST), Other Backward Castes (OBC). Forward Caste is synonymous to 'General' class which is used often in India. The basic difference from the point of view of Indian government is that SC, ST and OBC are positively discriminated through reservation/quota in employment and educational institutions.

³Wealth and Consumption in this paper.

3 Data

There is neither any all-India level administrative household wealth data nor a caste census data publicly available, which makes the task challenging. Fortunately there are many all-India level large sample surveys to estimate statistics on wealth. Also under demographic particulars in surveys, some information on caste is available. Certainly surveys are not the best in capturing the information perfectly (as some part of the population is ignored. e.g homeless, prisoners etc), but it is the best possible source of information available. In this chapter I will describe in detail the different datasets I have used. Some datasets (like IHDS) is quite well known and have been well exploited by economists. I will briefly go through such datasets. However, some datasets are less known, like NSS-wealth datasets, which I describe in detail.

Since the study covers a long time period, several rounds of same surveys are used. Since these surveys are supposed to capture the same information, so at different points, one would expect them to be comparable. Unfortunately, often there are changed definitions, which makes a direct comparison difficult. I have made an effort to make different rounds of surveys comparable, but it is not possible in some cases. For example, there could be different type of biases coming from conduction of surveys by different agencies. One prime example in Indian NSS surveys is that on several occasions half of the sample is surveyed by agencies affiliated to central government and half by state government agencies. Due to differences in availability of resources the efforts in surveying can be different leading to some biases. Due to lack of time, I have not tried to assess such differences and assumed the bias due to such differences to be negligent. This is usually an accepted practice in literature. All other changes which I make are presented below in different survey blocs.

Since wealth surveys are prone to differential level of under-reporting (with high level of under-reporting coming from land and gold asset holders) and high concentration of wealth distributions at top end, I re-estimate the distribution using the Forbes data (Jayadev, Motiram, and Vakulabharanam, 2007).

3.1 NSS- All India Debt and Investment Survey (AIDIS)

The NSS AIDIS are decennial surveys for the years 1961, 1971, 1981, 1991, 2002 and 2012. It is the primary data source for generating the wealth inequality series. The survey began in 1951 when the RBI (Reserve Bank of India) started All-India Rural Credit Survey with the main objective of identifying the demand and supply of credit in rural India to formulate banking policies and schemes. Information on assets and incidence of debt on rural households were collected to assess the demand side of credit. The next round of survey called All-India Rural Debt and Investment Survey (AIRDIS) was conducted in 1961-1962. This round of survey, for the first time collected details on financial assets, but the survey was still restricted to rural areas. Nationalisation of Banks in 1969 gave a new shift to credit policy, focussing on the hitherto untouched people involved in entrepreneurship, retail trade, professional works etc. and this led to decision to extend the survey to urban areas in the third round of survey in 1971-72. This round also saw an organisational change which brought into place NSSO (National Sample Survey Organisation) to conduct the survey. Unfortunately due to some sampling issues the urban data was never published.

Methodology:

The methodology adopted for the collection of data in NSS AIDIS is different from the well known NSS consumption surveys. Each selected household is visited twice, once during the first half of the survey period and then during the second half of the survey period. The surveys are conducted during the calendar year for the reference period which matches with agricultural year of the country.⁴ The asset and liability on a certain fixed date (reference date) is ascertained. The reference dates are mid-point of the reference period. Depending on different rounds of surveys, the methodology for ascertaining the asset value changed slightly.

In 1961-62, the asset and liability of the household is derived on a fixed reference date (i.e. 31st Dec 1961 which is mid-point of the reference period July 1961-June 1962) by ascertaining the stock of assets/liabilities as on the date of survey and their transactions/flow during the period of date of reference and the date of survey. In 1971-72 the survey directly collected for the fixed reference date (30th June 1971 and 30th June 1972). In 1981-82, the information on the stock and flow of assets was similar to 1961-62, with changes in valuation.

The details of stratification in different rounds of surveys are provided in Appendix (Stratification in NSS AIDIS). The important thing to note is that before the 1991 round of survey, households were stratified only on the basis of land possession (primary asset of household wealth). Later research found that the liabilities/debts were not captured properly due to stratification based only on assets. The correction was made from 1991 onwards in the stratification method using land possession and indebtedness status of households in rural areas. For urban areas, monthly per

⁴For e.g 1961-62 survey collected information from Jan-Dec 1962 for the reference year July 1961-June 1962. Agricultural year in India is from July to June. Similarly for 1971-72 survey, the survey was conducted during Jan-Dec 1972 for the reference period July 1971-June 1972. And so on for later years of 1981, 1991, 2002 and 2012

capita expenditure and indebtedness status were used.

Assets:

Assets include all items owned by the household which had some money value. The survey has collected the information on inventory of assets and liabilities on a fixed reference date. The definition of assets has gone through changes in different years. Physical and Financial assets are the two broad categories. In 1961-62 total assets included the value of 8 different types of assets- i) Ownership rights in land ii) Special rights in land iii) Buildings iv) Livestock v) Implements, Machinery, Transport Equipments etc vi) Durable household assets (life more than a year and which can't be purchased at a nominal price) vii) Dues receivables on loans advanced in cash/kind. viii) Financial assets-Government securities, National Plan savings certificates, shares etc. Importantly no information on cash was collected. In 1981-82, Agricultural implements and non-farm machineries including transport equipments were collected separately. However, crops standing in the fields, cash in hand or stock of commodities were not considered as assets. In 1991-92, non-farm business equipments and all transport equipments were collected separately. Unlike previous years there was an effort to collect information on cash in hand of the household. Similar definition and categorization was used in 2002 survey. Bullions and Ornaments were also collected as part of assets. In 2012-13, survey excluded some of the assets which it had collected before. Household durables were excluded on the pretext of valuation concern. Bullions and ornaments were also not collected.

Valuation of Assets:

Estimating the total wealth requires not only the number/amount of assets but also their valuation. In 1961-62, all the values of the physical assets were evaluated using the fixed average market value prevalent at the time of the first round of the survey. Dues receivables were evaluated using average wholesale prices. Shares were valued at their paid-up value and all other financial assets were evaluated at their face values. There was a slight change in 1981-82 in the valuation. The value of physical assets owned on the reference date was simply the value on the date of survey minus the value of transaction between the reference date and the date of survey. Essentially it means different prices for the same assets were used.

Due to the lack of book value for valuation of assets for household sector, the following procedure is followed:

- i) Value of physical asset acquired prior to the 30th June 1981 (1991, 2001, 2011) was evaluated in its existing condition at the current market price prevailing in the locality on the date of survey if the asset is owned on the date of survey or on the date of disposal if the asset is disposed of during the reference period in a manner other than sale.
- ii) In case the asset is sold/purchased during the reference period, sale/cost price is considered as value of the asset. If the asset is acquired by way of construction, the expenditure incurred on construction is taken as its value.
- iii) If the asset is acquired other than purchase, then the value of the asset in its existing condition as prevailing in the locality at the time of acquisition is noted.
- iv) If the asset is acquired during the reference period and is also disposed of during the said period, the disposal value is reported

Availability of the data: Micro-individual survey files are available for the last three rounds of survey- 1991-92, 2002-03 and 2012-13. For previous surveys, only source of information is annual reports. The 1981-82 and 1971-72 reports are available⁵. The 1961-62 report is not digitised yet and is available in hard copy format.⁶ The samples are fairly big in size and vary for different years. The assets are collected at household level in all the surveys. I decided to work with individual level wealth as it provides a better understanding of wealth distribution from the perspective of inequality study. For example, a statement like top 10% of the households own 50% of wealth is a weaker statement to make in studying inequality if those 10% happened to represent 50% of total population. Household level inequality hides the per-capita level information, which is better suited for inequality statistics. Since there is no standard method to divide the wealth within household, I equally split among adult household. This will hold true for most of the physical wealth (like land, building, transport etc) which is synonymous to public goods within household. This procedure allows global comparison of inequality statistics. Equal split within a household is a big assumption in Indian society- where women usually do not own wealth because of various reasons like customary transfer of wealth from father to son, biased gender inheritance laws⁷ and general gender discrimination in India, but usually have a say (even if unequal) in managing at the household level. The social norm of primogeniture also leads to unequal share of wealth - major share of inheritance going to the eldest son. The definition of adult population is chosen as (> 20 years) for all the analysis.

In all the analysis related to wealth using AIDIS datasets, adult individual is the basic unit of reference. One of the issue is that the tabulated data for surveys are provided at household level. For converting the wealth values at individual level, I use decadal growth rate of household adult size from next round surveys, for which micro-data is available. The decadal rate of change in HH adult size in 1991-2001 is assumed to be same in 1981-1991 by decile.

⁵<http://www.mospi.gov.in/download-reports>

⁶The library of College of Agriculture Banking, Pune, has the report and it is accessible on prior appointments.

⁷Before Hindu Succession Amendment Act 2005, women were deprived of inheriting land and other properties.

I use a correction factor- to make the estimated data consistent at macro level population. Full detail is given in Appendix “Converting from Household Level to Individual Level”.

Justification for using total wealth instead of net wealth Further the distribution is estimated with household per capita total wealth and not with household per capita net wealth. Net wealth is total household wealth minus total household debt. The debt level from AIDIS are suspected to be unreliable due to reasons of strong tendency of under-reporting of liability, issues related to sampling methodology and relative increase in state sample compared to centre sample Chavan (2008) and Narayanan (1988). Comparing the debts handed out by commercial banks, cooperatives and other lending agencies, Gothoskar (1988) found under-estimation of 40% in 1971-72 round and 50% in 1981-82 round. The other reason to use total wealth is that for pre-1991 surveys the information is only available in tabulated form which restricts estimation of distribution of net wealth as the classification is by total asset ownership and not by net wealth status (Subramanian and Jayaraj, 2008). Due to these issues, I work with household total assets instead of household net assets.

3.2 IHDS- Indian Human Development Survey

IHDS - is a nationally representative panel survey for the years 2005 and 2011. It is a joint venture of University of Maryland and National Council of Applied Economic Research (NCAER). The survey collects information on income which is not captured in other household surveys in India. Further it provides information on Brahmin caste- a sub-group within Forward caste- which is unavailable in NSS surveys. This paper uses the cross-sectional aspect of the dataset⁸ for two purposes.

First to produce general socio-economic characteristics of different castes in India and perform a comparative analysis using the latest round of survey- IHDS 2011-12.⁹ The survey sampled 42,152 households with 2,04,568 individuals interviewing the head of the household to get this information. I create caste group based on religion and caste codes based on the following combination- a) Dalits (SC), Adivasis (ST) and OBC's (Other Backward Castes) are coded as they are, regardless of their religion; b) Next Brahmins are coded as Brahmins. c) Next all Hindus¹⁰ who are not categorized above are coded as Forward Caste (FC); d) Next, all the Muslims, who are not yet coded are coded as Muslims. e) All the rest of the population is grouped as Others.

I would like to highlight that this classification is different from the one given in IHDS. I chose this categorization, since SC, ST and OBC have some provisions of positive discrimination¹¹ from central and state governments which directly impacts the educational and income outcomes.

4 Demographic Profile

India is the second most populous country after China and 7th largest in terms of area. India is full of diversity. India has 29 states with 1.3 billion population. The largest state of India has more than three times the population of France. It is one of the oldest civilisations in the world, and is the birth place of four existing religions of the world- Hinduism, Buddhism, Jainism and Sikhism. It also has the third largest Muslim population in the world. There are 22 national languages and a caste system with ~ 4000 castes. Religion, race, caste and language not only determine personal identity but also play an important role in many economic decisions, both at household level and at national level. It became a secular, democratic country and adopted a socialistic pattern of production after becoming an independent nation in 1947 and is now transitioning towards a capitalist system. All these demographic, social, political and economic factors have some contribution towards the existing “Indian form” of inequality.

This chapter outlines the evolution of basic demographic profile of India in 1901-2011. The hundred years time period provides a long term evolution of population structure. Understanding of inequality in India will be incomplete without taking into account its societal structure. The demographic patterns across different religion and social groups are estimated using survey data and the Census. Census was started in India in a regular manner from 1881 onwards. One has to be cautious while looking at the data from the pre-independence era. The British territory has seen a gradual expansion in India and some of the differences in population is due to different areas mapped under Census.

⁸I intend to use the panel structure of the dataset in my future research on understanding the evolution of different economic outcomes for different castes

⁹I refer IHDS 2011 in the whole document. The survey was conducted between Nov 2011-Oct 2012

¹⁰There are 5 major religions in India-Hinduism, Islamism, Christianity, Buddhism, Sikhism

¹¹usually termed as reservation in India- as 15%,7.5% and 27% of total seats are reserved for SC, ST and OBC respectively in all the government educational institutions and government employment positions. SC, ST and OBC are sometimes also referred as reserved castes.

The first attempt of conducting the census was between 1840-65 and it covered only the three big cities of that time- Bombay, Madras and Calcutta. Later at the time of independence of India in 1947, India was partitioned and two nations were formed out of it. The partition was along religious lines and resulted in a change of the population mix in terms of religion.

The total population of India grew from 253.9 million in 1881 to 1210.7 million in 2011. As per Thomson-Notestein-Blacker classical demographic transition, India was in Pre-transitional phase of very high crude birth rate (CBR) and crude death rate (CDR) at > 40 per thousand till 1920, and the population was almost stable. The small increasing population of Census data is mainly on account of increasing covered area. India entered into second phase of the Transition in 1920. The CDR started falling after 1920 but the CBR remained high till 1960's. The gap between CBR and CDR resulted in population growth. The life expectancy also increased from less than 20 years in 1911-20 to over 40 years during 1951-60. The decline in CBR started from 1960's (start of Middle transitional phase) and it dropped to 22.1 in 2011. The total fertility rate (TFR) reached just above replacement level at 2.4 in 2011. The period during 1970-2011, saw a consistent decline in CBR, but the difference between CBR and CDR resulted in population explosion during this phase. Now India is considered to be in the Late Transitional phase, where CDR has stabilised and CBR/TFR is continuously declining. The population of the country has increased 3.35 times its population in 1951. The rate of growth was lowest in 1921 and accelerated after 1951 with decadal increase of 20% during 1961-2001. It is only in last census decade that the rate of growth has declined to 17.7%

4.1 Population Share- Rural Urban divide

The urbanisation level in India has grown from a level of 10.8% in 1901 to 31.2% in 2011. It is still a rural dominated country and the urbanization level is much lower than what is experienced in developed countries. France US, UK all have urbanization level as high as 80%. The urbanization level is very low even compared to developing nations like- China (55%) South Africa (65%), Russia (74%). It is even lower than the urbanisation level in partitioned countries- Pakistan (38%), Bangladesh (34.3%). India still is a country of villages where more than 65% of the population resides. Table 1 provides the evolution of urban population share in the country in long run.

Table 1: Rural Urban Population Share

Census	Year	1901	1911	1921	1931	1941	1951	1961	1971	1981	1991	2001	2011
Population %	Rural	89.16	89.71	88.82	88.01	86.14	82.71	82.03	80.09	76.66	74.28	72.17	68.84

Source: Census data.

The share of Rural and Urban population in NSS consumption survey in 1983-2009 is provided in Fig. 11. We can notice a slight difference from the census figures. Urban area is slightly over-represented in the data. The definition of Urban area is the same as used in Census.¹²

4.2 Population Share by Religion

India has residents from all the religions. Islam and Christianity are imported religions to India and Buddhism, Jainism and Sikhism have their origin in India. The above mentioned 6 religions, makes up for more than 99% of Indian population Hindus are in majority in the country. One important remark on aboriginals or people from Schedule Tribe (ST) populations in the country is that before the census, they were categorized separately from Hindus. Post independence they are clubbed under Hindus. The estimate of ST population is provided later. They are captured in the census under Hindu religion. The population proportion is almost constant except a decline in Hindus share and increase in Muslims share.

Table 2: Religion-wise Population Share

Religion	Census Years																
	1840-65	1860-69	1867-76	1881	1891	1901	1911	1921	1931	1941	1951	1961	1971	1981	1991	2001	2011
Aboriginals	0	0	0.28	2.53	3.23	2.92	3.28	3.09	2.36	6.58

Source: <http://dsal.uchicago.edu/copyright.html>.

¹²The definition of Urban area depends on 3 criteria namely- 1) Population threshold (≥ 5000) and density (400 sq.km) 2) Proportion of men in agriculture sector (75%) 3. Presence of Municipality/Municipal Corporation.

4.3 Population Share by Caste

Define caste: Caste is a system prevalent in India society which can be thought of as a practised version of varna system enumerated in religious scriptures. There is enormous literature on caste in sociology and anthropology (Kannabiran, 2009). I will describe certain essential components of caste system which still have relevance today. I define in detail some features of the caste system.

First- Caste system is not only a Hindu religion phenomena anymore though it indeed has its beginning in Hinduism/Brahmanism way of living. It has now entered into all the religions in India, in one or other form. It is believed that Buddhism and Jainism, the two ancient religions of India were born in around 5th century B.C against the backdrop of high levels of social inequality that generated from discriminatory norms of Brahmanism of that time. With time these religions themselves acquired the prejudiced traits of Brahmanism. The decline of Buddhism in its own birthplace is often associated to this reason.

Second- caste system is not varna system. Varna system has 4 (or 5) categories namely Brahman (priests, scholars and teachers), Kshatriya (rulers, warriors and administrators), Vaishya (agriculturists, merchants) and Shudra (workers / small farmers / service providers), and it has its origin in Dharamshastras¹³. The fifth category consisted of Untouchables. The first three categories were allowed to wear the sacred thread and study religious texts. Even though caste system is believed to have come from varna system, both of them are not identical. Today society associates more with caste (or jatis in Hindi), which are thousands in numbers and vary regionally. (Srinivas, 1955) says that these thousands of castes can be clustered around varnas. This makes comprehension easier.

Third- Caste system has broad acceptance in the society. It is not a menace in the opinions of majority of the population. It acts as an identity and beyond that it provides some of the benefits which the welfare state provides (Srinivas 2004). For all the practical purposes, there is very less competition inside this system to outrank others, because caste is determined by birth. The top-most rank is reserved forever for the perceived creators of the system - Brahmins.

Fourth- Caste system provides a form of social status to every caste. Indeed, as with any form of status, it comes at some cost. Some castes derive higher status tag at the expense to lower status tag to others. However, it is more generous in the sense that the higher status has been distributed to fairly large proportion of population. 5% Brahmins and around 5-7% Rajputs (from Kshatriya of varna), Bania (2%) are considered higher castes. It could be surmised that the most important and unique factor which provides sturdiness to the caste system is the fact that it assigns relative position to every caste in the society. Even though Rajputs come second in hierarchy, they are on top of 90% of the population. Similarly Banias derives utility by being higher in status to 88% of the population. And this way the caste system has created a situation where all the castes (except the ones at bottom) derive some kind of superior social status compared to other castes.

Overall the debate on caste system has remained contentious. The most famous debate in recent history is the Gandhi-Ambedkar debate on caste. Gandhi (considered as father of the nation) was against the discriminatory nature of caste system. He coined the term Harijans (in Hindi it means-children of God) for untouchables and worked throughout his life for their upliftment. However, he was not against the caste system itself. According to him, division of labour is inevitable in society and there was no need to overthrow the caste system which was based on division of labour. On the other hand, B. R. Ambedkar (architect of Indian Constitution) was against the stratification of society based on caste. He made a distinction between division of labour and division of labourers, where the first one is choice-based and the later imposed by the caste system. He said that outcaste is a product of caste and unless caste system is uprooted from its base, the discrimination based on caste will remain. Hence he demanded complete overthrowing of the system. In principle, I would agree with the Ambedkar stance on the caste system, however one cannot ignore the reality of the society. The difficulty to overthrow the system is its huge approval in society. One of the peculiar aspects of the caste system, which has become the strongest pillar of its existence, is caste endogamy. Everyone is supposed to marry within one's own caste. This paper finds strong evidence of caste homogamy in the society, where 94% of total marriages are within-caste marriages.

Caste became part of census in full fledged manner in 1901 census. The historical census data at caste level is available online at Digital South Asia Library (University of Chicago)¹⁴. Table 3 provides top 20 castes which existed in 1901 and 1911.¹⁵The last census which gathered caste data and is available in public was in 1931. Indian government wanted to stop caste-based census due to the fear of re-enforcing the caste identity. However provision of affirmative

¹³ Manusmriti- the first one to be translated in English by Britishers in 1784 to rule Hindus in India. I wonder the impact of this colonial act in reinforcement of caste system in the form it is today.

¹⁴<http://dsal.uchicago.edu/copyright.html>

¹⁵The data of caste for 1921 and 1931 census is much elaborate and is not in csv format. I am working to handle it

actions were made for Scheduled castes (Dalits) and Scheduled Tribes (ST) since 1951. Scheduled caste (SC) was not a single caste entity but a list of castes. The people belonging to castes in SC were considered untouchables during that time. They formed the lowest rung in the caste hierarchy. For the implementation of the clauses of positive affirmation enshrined in the constitution, census gathered information on SC and ST. Later in 1990, India extended the caste-based positive affirmative actions (also referred as reservation policies) for Other Socio-Economic Backward Class of the society. These are the population often coming from Other Backward Castes (OBC) castes. Again OBC is not a single caste but a list of thousands of castes. When the reservation policies was promulgated for OBC's, there was a major problem in estimating the population of OBC's, because there was no census information. OBC population was estimated from 1931 census using the population growth. Facing the problem of lack of information on castes, Indian government conducted the Socio-Economic Caste Census in 2011 to update the knowledge on different castes. However, unfortunately the data has not been made public.

Table 3: Population Share - Census

1901			1911		
Caste	Population Size	Population %age	Caste	Population Size	Population %age
Shekh	28,708,706	9.16	Sheikh	32,131,342	10.25
Brahman	14,893,258	4.75	Brahman	14,598,708	4.66
Chamar	11,137,362	3.55	Chamar	11,493,733	3.67

Lingait	2,612,346	0.83	Jolaha	2,858,399	0.91
Koli	2,574,213	0.82	Palli	2,828,792	0.9

Source:<http://dsal.uchicago.edu/copyright.html>.

As per Census data¹⁶ the proportion of SC in population has increased from 14.67% in 1961 to 16.6% in 2011. During the same time period the proportion of ST has increased from 6.23% to 8.6%. Apart from natural growth rate of SC and ST, classification of more castes/tribes into SC/ST¹⁷ has contributed in the increase of their population share. Apart from the Census, surveys too provide valuable information on the estimates of population. The Census is conducted once in 10 years and the NSS consumption surveys are conducted almost every 5 years. Hence NSS surveys in a way complement the Census and can be utilised to study mid-year variations in the population profile. Post 1999 NSS surveys allow the breakdown of the population into OBC also. I categorize the population based on a combination of religion and caste which has been mentioned in a section of the IHDS dataset. The same definition has been used in NSS also.¹⁸ Fig. 1a depicts the evolution of population share of SC, ST, OBC and FC since 1983. We can see that SC and ST are slightly over-represented in the survey (SC- 20% and ST -10%). We also observe an increasing share of OBC population share and corresponding decreasing share in population of FC. Non-Hindu population share declined in 1999, because of the creation of the OBC category. OBC Muslims are categorized under OBC.

¹⁶<http://censusindia.gov.in/>

¹⁷The recent most addition is in 2015. <http://pib.nic.in/newsite/PrintRelease.aspx?relid=115783>

¹⁸1. SC(Scheduled Caste) 2. ST(Scheduled Tribe) 3. OBC(Other Backward Castes) 4. FC(Forward Castes-Hindus who are not SC/ST/OBC) 5. Non-Hindus

Figure 1: Population Share from NSS

(a) Proportion of SC/ST/OBC/FC

(b) Share of Hindu in different castes

The share of different caste groups in Rural, Urban sector separately is provided in appendix Fig. 12. We observe that FC community is disproportionately concentrated in Urban areas and STs are mainly confined to Rural areas.

The second subgraph 1b shows the proportion of Hindus in SC, ST and OBC. It is important to re-iterate here that SC, ST, OBC which are reserved communities in India (with positive affirmation) are not restricted to just the Hindu population. Caste has intruded into other religions also. We see an increase of other-religions in ST and OBC. In 1983, Hindus comprised almost 90% of ST which dropped to 86% in 2009, whereas for the OBC the share of Hindu population dropped from 88% to 84%.

IHDS datasets allows to split FC category into Brahmins and rest of the FC, which help in estimating the population share of Brahmins ($\sim 4.86\%$) and some of their general demographic and socio-economic characteristics. Table 13 provides the percentage of population in different caste groups. The information on Brahmin community which is considered as the highest caste in the caste hierarchy makes this table interesting. As there is no census on castes, surveys are the only source to gauge their population share or other characteristics. Another important observation is that child and young population among SC, ST and OBC is higher than their respective population, whereas adult and old population of FC is higher. This hints towards decreasing fertility level of FC.

Another nationally representative dataset namely, NFHS(National and Family Health Survey) allows to further split the FC into different castes.¹⁹ Table 14 provides the population shares. I split FC into Brahmins (4.7%), Rajputs (proxy for Kshatriya- including Marathas 4.9%), Bania (2.1%), Kayasth (.6%) and Others (9.3%). The population share of Brahmins here is close to what we get from IHDS dataset- which is a good sign for the categorization. The observation on fertility holds for other FC groups too. They have higher proportion of adults and are older compared to their overall population share.²⁰

Comparing with 1901,1911 Census we see almost same proportion of Brahmins after almost 100 years! Rajput+Maratha population proportion is also very close to what it was a century ago. Bania population is higher in NFHS, but it could simply be due to categorization of more castes into this category. Business as a profession has been adopted by other castes and those castes have now been associated with Bania community.

The next few figures in the Appendix (13 and 14 show the proportion of SC/ST/OBC in different religions in surveys. Pre-1993 surveys have no categorisation such as the OBC. In Hindus the share of SC and ST is almost stable at around 9.5% and 19-21% respectively and they are slightly over-represented in the survey compared to Census estimation. For later rounds we see in 1999, OBC's formed 38%, 30%, 20%,13.6% in Hindu, Muslims, Christians and Sikhs respectively which increased to 43%,43%,25%,21% in 2009 in the same order. The increase in OBC population is in all religion which is chiefly is due to reclassification of more castes into OBC. The potential demographic reasons like - growth rate, migration etc. usually would take longer time to translate into such big changes.

¹⁹Currently the categorization is based on google searches, crowdsourcing etc. It is prone to biases and hence I am working on basing these categorization on some historical authentic sources.

²⁰All the castes categorized into Brahmins, Rajputs, Bania and Kayasths are categorized is given in appendix.

4.4 Economic Characteristics of different Castes

IHDS and NFHS datasets are utilized to compare the socio-economic characteristics of different castes. IHDS datasets has the additional benefit of being a panel dataset to understand changing conditions over 20 years. Also it is the only dataset which captures income. I intend to perform a panel data analysis in my future research. However, for the purpose of this paper, I restrict my analysis to a cross-sectional one.

4.4.1 Economic Aspects

Table 4 shows the mean values of basic economic and educational characteristics of different caste groups. The values are given at both household and per-capita level. It provides a clear picture of stratification in the society. The second last column ‘‘Others’’ contains the rest of the population which belongs to the Non-Hindu, Non-Muslim religion group and does not fall under SC/ST/OBC. This is a rich minority cluster (with only $\sim 1.5\%$ population) in terms of all the economic and educational parameters. The last column shows the all-India statistics.

Income: Average annual income of an household in India is Rs.113,222(Rs. $\sim 9,435$ per month). The annual income of ST and SC group stands at 0.7 times and 0.8 times lower than the all-India average income. OBC and Muslims both have around 0.9 times household income of the overall average income. Forward castes (FC), have average household income at 1.4 times the all-India income (with a slight difference between Brahmin and Non-Brahmin). There is sequential inequality (SI) based on average income with ranking $ST < SC < Muslim < OBC < \text{OVERALL} < FC(\text{Non} - \text{Brahmin}) < FC(\text{Brahmin}) < Others$ trend. We see a similar trend at per-capita level of annual income. The standard deviation which is not present in this table is highest for Others followed by FC(Non-Brahmin), FC(Brahmin), SC, Muslim, OBC and ST.

Wealth: Wealth/Assets in IHDS is simply the average of indicator (=1) of the presence of for 33 different household durable goods like TV, Air Conditioning, 4-wheeler etc. It has a range of 0-33 and is defined at HH Level. The SI based on assets across different caste groups is visible with ranking $ST < SC < Muslim < \text{OVERALL} < OBC < FC(\text{Non} - \text{Brahmin}) < FC(\text{Brahmin}) < Others$, which is similar to income trends.

Consumption: The consumption data shows similar pattern with OBC and Muslim groups near the all-India average, SC and ST below average and both Brahmins and non-Brahmins performing better.

Table 4: Wealth,Income and Consumption Mean Values-IHDS 2011

	SC	ST	OBC	FC(Brahmin)	FC(Non-Brahmin)	Muslim	Others	OVERALL
Annual Income of HH (in Rs)	89,356	75,216	104,099	167,013	164,633	105,538	242,708	113,222
Per Capita Annual Income (in Rs)	19,032	16,401	21,546	35,303	36,060	20,046	56,048	23,798
Annual Consumption of HH (in Rs)	87,985	72,732	108,722	146,037	143,497	102,797	181,546	109,216
Per Capita Annual Consumption (in Rs)	18,740	15,860	22,503	30,869	31,430	19,525	41,924	22,956
ASSETS	12.7	10.2	14.7	18.2	17.9	13.3	22.2	14.6
ASSETS2005	12.2	9.9	14.2	17.5	17.1	12.9	21.2	14.1
Highest Adult Education	6.7	5.9	7.8	11.5	10.3	6.6	11.6	8.0
Highest Male Education	6.3	5.6	7.5	11.3	9.9	6.0	10.5	7.6
Highest Female Education	3.9	3.3	5.0	8.6	7.8	4.6	10.0	5.3

Source: Author’s calculation using NFHS IHDS 2011 datasets. Design weights are used to estimate these values.

Using NFHS 2005, we can compare between more caste groups in FC. Table 16 in Appendix presents the wealth index provided in the dataset, categorizing the population in 5 brackets from Poorest to Richest. We see that 50% of the Brahmin, 31% of Rajputs, 44% of Bania and 57% of Kayasth fall in richest category. For other caste groups only 5% ST, 10% SC, 16% OBC, 17% Muslims fall in richest category.

I find a high level of sequential inequality in society, which implies clustering of social groups. FC is clustered more towards higher income/consumption/wealth values. OBC and Muslims are in the middle and SC/ST cluster towards the lower end. This clustering of different groups is parallel to the caste hierarchy with FC the highest caste and SC/ST the lowest in hierarchy. Economic ranking follows caste hierarchy, making caste a valid stratification in the society. It is important to keep in mind that the standard deviation is also very high in FC groups, i.e. not all are well off in that group. The clustering of social groups is not perfect.

4.4.2 Education

The last three rows of Table 4 depict the highest level of education for adults, males and females among different caste groups.²¹ Brahmins have highest adult education followed by Others and FC (Non-Brahmins). The comparison for adult education across different community gives- $ST < Muslim < SC < \text{OVERALL} < OBC < FC(\text{Non} - \text{Brahmin}) < FC(\text{Brahmin}) < Others$ The difference between Brahmin and ST is 5.6 years, Brahmin and Muslims is 4.9 years, Brahmin and SC is 4.8 years, Brahmin and OBC is 3.7 years and Brahmin and Other FC is 1.2

²¹0-16 with 0 denoting no education, 12- Higher Secondary 15- Bachelors, 16 above Bachelors.

years. Muslims who are almost near the overall average in economic parameters fall behind the SC group in terms of education.

Taking note of the highest male and highest female education pattern separately, we observe same trend among caste groups as we saw for the highest level of adult education. This shows the different trajectory of education curves among different caste groups. Another important point to note is that among all the social groups, women have lower mean education than men. There is a **secular gender discrimination** in the society. This shows a different trajectory of education curves between men and women in every social group. The interaction of different trajectories of education curves among social groups and among sexes are potentially a crucial determinant in shaping up inter-caste and inter-religion marriages. I explore this in detail in chapter on Assortative matching. Comparing among females, FC (Brahmins and non-Brahmin) communities have the highest average years of education, implying these caste groups are sending more of their girls towards schools and colleges.

Using NFHS 2005 I compare the education level of adult in other Forward castes [Appendix Table 17]. Kayasth with 12.3 years of education is highest, followed by Brahmins (11.9years), Bania (10.3 years), Rest of FC(9.16yrs) and Rajput (9.05 years). The qualitative comparison is same as found in IHDS datasets, though there is slight change in average years of education.

Within SC/ST/OBC Analysis: I look within the SC/ST/OBC category to see if there are differences across different religion groups. The table 5 presents the relative performance of the groups with respect to all-India average values. We can see that within ST, Christians have 1.6 times income and assets than all-India average and their educational level is better than many other groups. Muslim ST's economic parameters are closer to all-India average but education wise they are behind. Hindus and Other/No religion ST's which forms 78% and 12% of all ST's are the worst performing groups.

In the SC group, Hindu (93%) and Others (6%) are two major groups and we see that SC's from other religions have outcomes at par with the all-India level. Hindu SC's have worse outcomes and their mean assets have declined from 2005, which is a worrying issue.

In OBC, the two big groups are Hindu (82%) and Muslim (16%). Hindu OBC's have better educational averages than Muslim OBC's. On the economic scale they look almost the same. The small group of other religion in OBC's are in no way backward.

Table 5: Within SC/ST/OBC Relative to all-India: IHDS 2011

	ST				SC			OBC		
	Hindu_ST	Muslim_ST	Christian_ST	Others_ST	Hindu_SC	Muslim_SC	Others_SC	Hindu_OBC	Muslim_OBC	Others_OBC

5 Wealth Inequality Series

This chapter illustrates the distribution of wealth among households in India. Instead of using gini coefficient as a single measure of inequality, the emphasis is on estimating different shares of wealth in top 10%, middle 40% and bottom 50% of the population (Piketty, 2014). This distribution of wealth is also examined among different caste groups. Previous chapter has already established the stratification in society along castes from simple economic parameters. In this chapter, the focus is entirely on wealth, which is associated with welfare, a tool for consumption smoothing, a source of power and contribution in total income through asset income (rent). Micro-files allow for more detailed analysis, like age and education profile of different strata of the society.

I have made an effort to look into the issue of wealth inequality from social point of view. Distribution of land is analysed in detail. Land happens to be the most important asset of Indian households in monetary value. India has tried in the past to achieve an equitable distribution of land with various land reform measures.²² Today the slogan of "land to the tiller" has died down in India partly due to decline in the number of big land sizes (population explosion has a major role in division of land plots, long drawn court cases by landowners to stall the land reforms etc.) and partly because of arrival of new opportunities in manufacturing and service sectors. Unless India develops different

²²Zamindari Abolition Act 1954, Land Ceiling Act, Tenancy reform act etc.

forms of assets, the issue of unequal distribution of land can't be neglected. The distribution of wealth in different social/caste groups has been studied with an attempt to characterize the evolution of the pattern. Representational Inequality-i.e. lower presence of a certain caste group than its proportionate share in the population has been exploited in Section 5.2, apart from the top share statistics. Both across-castes and within-caste inequality have been examined in detail. The dichotomy between rural and urban sectors has been highlighted across all the outcomes.

The methodology in estimating the top share is still new and evolving. The limitation of surveys in capturing top wealth holders is dealt in two ways- 1)By using Forbes millionaires data and making an assumption of Pareto distribution at top percentiles.(Blanchet, 2016; Garbinti, Goupille-Lebret, and Piketty, 2017) 2) A novel attempt to re-estimate the inequality in selected urban areas²³.

The results are accompanied by discussions which is an attempt to look for the reasons in past and current government's economic and social policies. The trends and evolution has been analyzed in detail. The discussions part in every section mentions potential future research.

The chapter begins with providing a description of the contribution of different assets in the total household wealth at all-India, Rural and Urban sector separately (Table 6).

Table 6: Contribution of different assets in total Wealth

Contribution of Different Assets in Wealth (excluding Durable HH's)														
Type of Assets/Year	Rural						Urban				All-India			
	1961	1971	1981	1991	2002	2012	1981	1991	2002	2012	1981	1991	2002	2012
Land	66.49	69.92	66.92	68.12	65.00	69.84	38.21	40.04	41.62	45.26	60.06	59.33	56.59	56.36
Building	22.52	18.76	22.31	22.69	24.28	20.33	41.98	44.34	40.92	43.24	27.00	29.47	30.26	32.89
Livestock	8.00	6.81	5.39	3.58	4.35	1.55	0.94	0.48	0.47	0.10	4.33	2.61	2.95	0.75
Agricultural Machinery, Equipments and Transportation	2.99	2.83	3.99	3.99	3.99	2.70	5.90	5.36	6.76	3.17	4.44	4.42	4.99	2.96
Financial Assets	-	1.15	1.29	1.56	2.28	5.46	12.50	9.30	9.94	7.96	3.97	3.98	5.03	6.83
Loan Receivables		0.52	0.11	0.06	0.10	0.12	0.47	0.49	0.29	0.28	0.19	0.19	0.17	0.21

Looking at all-India verticals, we see that *Land* value share is the highest but is on a gradual declining trend. The share has declined from 60% in 1981 to 56% in 2012. Rural sector expectedly has land as the most valued asset and it has almost remained at around $67\% \pm 3\%$ since 1961. This hints towards continued existence of lower material wealth in rural sector. In Urban sector, land share is lower than all-India level but it shows an increasing trend from 38% in 1981 to 45% in 2012.

Building is the second most important asset in the wealth. It is surprising to note that Land and Building together form 90% of the total household wealth. The decline in land share is accompanied by increase in the Building value share. In Rural area, the share of building has hovered around $20\% \pm 2\%$ except in 2002 when it is at 24%. The rural village morphology allots only a small share of land area towards living and common space²⁴ Most of the land is dedicated to cultivation. In Urban area, building share is almost double than that of rural area at around $42\% \pm 2\%$. The stagnancy in the building share might look surprising as in many cities the advancement of apartment culture is accompanied by high rise in building prices. One possible explanation is almost equivalent increase in land prices which has not let the building share in total wealth rise.

Financial Assets has the third largest share and it has increased to almost 7% level in 2012 from 4% in 1981. This is in contrast to high level of financial assets in developed countries. For example in France and US the share of financial assets stood at 30.9% and 48.3% in 1979.²⁵ There is a declining trend in the share of financial assets in Urban areas which is surprising. To some extent the decline can be explained by the change of definition of financial assets (explained in data section) in different rounds of survey. Non-reporting/non-inclusion of rich households could be another potential reason.

The supremacy of physical assets over financial assets is undoubted. Financial assets is a very small small part of total household wealth.

Agriculture Machinery, Non-Farm Machinery and Transport Equipements comes next in the descending list of contribution to total wealth. It's share has declined from 4.4% in 1981 to 2.96% at country level. In Rural area this component remained stable at almost 4% for 3 decades before dropping to 2.7% in last survey. Urban area, has seen a decline from 5.36% to 3.17%.

Livestock used to be around 3-4% of total wealth till 2002 before dropping to 0.75% in 2012. This decline is solely attributed to Rural areas where we see a decline of 3 percentage points. Interestingly in 1961, the share of livestock was more than the share of financial assets in 2012. The Livestock survey of NSS in 2012, found a decline of 26

²³I am thankful for this idea to Professor Abhijit Banerjee.

²⁴The rural roads inside villages in Northern India are kept so thin that sometimes passing two cycles from opposite directions at one time is not possible.

²⁵Kessler and Wolff, 1991.

millions (around 10% of 2002-03 level) bovines in 2012-13. This could be the reason for low share of livestock wealth. However, livestock from only those households which had some operational holdings of land²⁶ were surveyed which could potentially driving this decline.

The evolution of average per capita wealth (APCA) is given in Table 7.²⁷ We can see APCA is increasing since 1961 and the increase is faster in recent years. In Rural areas, till 2002 there is only a modest increase from Rs.50.8k in 1961 to around Rs.180k in 2002. This figure jumped to Rs.390k in 2012 which is $\sim 117\%$ growth in a decade or $\sim 7.5\%$ annual growth rate from 2002-12. Similarly in Urban area, we see a steep increase after 2002. The APCA in Urban area has increased from 272k in 2002 to 904k in 2012, implying an increase of 232%, or $\sim 12.7\%$ annual growth rate. The Urban-Rural gap in APCA is consistently increasing since 1981. The ratio of Urban APCA to Rural APCA has increased to 2.32 in 2012 from 1.25 in 1981.

Table 7: Per-Capita Average Wealth

Average Wealth - AIDIS					
Year	Price Level 2012		Nominal Level		Ratio=Ur/Rur
	Rural	Urban	Rural	Urban	
1961	50,836		1,369		
1971	56,118		2,748	-	
1981	86,388	108,785	10,874	13,693	1.26
1991	146,575	195,096	36,860	49,062	1.33
2002	180,655	272,443	96,011	144,794	1.51
2012	390,223	903,895	390,223	903,895	2.32

Source: Author's calculation using NSS AIDIS datasets. Design weights are used to estimate these values. Wealth Price Index is used to bring the prices from nominal to 2012 price level.

Overview of wealth along Caste in AIDIS

Surveys have usually slightly different composition than the population from Census population. Table 18 shows that ST formed 8-9% of total population and SC formed 18%-19% of total population. The information on OBC is present only for 2002 and 2012 survey. The proportion of OBC increased from 40.28% in 2002 to 43.57% in 2012 i.e. almost an increase of 3 percentage points. Correspondingly we observe a 2% decline in FC share and 1% decline in Muslim.

I check the share of total wealth and total land value share and found that SC/ST/OBC have lesser share than their population share. Table 20 presents the representational inequality for different castes.

At all-India level: SC suffers the worst in total wealth share as it owns only around 7-8% of total wealth which is almost 11 percentage points (pp) less than their population share. ST owns 5% – 7% of total wealth which is around 1-2 pp less than their population share. OBC group owns $\sim 32\%$ of total wealth in 2002 which increased only marginally in 2012 resulting in overall worsening of the gap relative to population share (-7.8% to -10.2%), due to considerable increase in their population share. On the other hand FC group share has shown an increase from 39% to 41% in their share in total wealth. Relative to their population share this group improved the gap from +14% to +18%.

Rural-Urban: The overall picture of relative gap between total wealth share and population share for different castes is similar in both Rural and Urban area as found at all-India level except few differences. First rural area seems more favourable for OBC group and less favourable to FC. In Urban area the sign of gap changes for ST group, i.e. they own more wealth than their population share. In 1991, 2002 and 2012, the relative gap is +1.12 pp, +2.24 pp and +1.72 pp respectively presenting urban area to be favourable to ST. I discuss representational inequality by decile in detail later.

Land has an important role in shaping up the overall wealth inequality in the country. The motivation to deal land inequality separately lies in the fact that half of the population still depends on land to get their primary income. The movement of people from agriculture towards manufacturing and service sectors is slower than the movement of GDP of India from agriculture to service sector. The contribution of agriculture and allied services declined from 51.45% in 1951-52 to 14.1% in 2011-12, whereas people dependent on agriculture was $> 50\%$ of the total population in 2012.

There is less representative inequality in *land area distribution* than what we saw above in total wealth. Table 21 provides the representational inequality at overall level among different caste groups. The total land area with ST which was 3.6 pp more than their population share in 1991 increased to 10.81% in 2012 at all-India level. There is no surprise that ST own more land as majority of them still closely live with nature in forests with large land area. The

²⁶Operational holding is different from Owned land. Land which is utilised for agricultural or other purposes by way of lease, tenancy etc is called operational holding.

²⁷I use WPI index to bring the prices at 2012 level for comparison across years.

big increase in 2012 survey is surprising. Forest Rights Act (2006) was implemented from December 2007, with the provision to grant legal recognition to the rights of traditional forest dwelling communities- almost all of whom will be ST²⁸. Land title rights was one of the rights. As per (Aggarwal, 2012), 1.1169 millions claim covering 3% of the forest area was recognized till 30th Apr 2011. OBC group has around 38% land area. SC is the worst in land area ownership. Second if we look at the *land value distribution* we go back to the same level of inequality as we observed in total wealth. The total land value share is 2 pp less for ST and Muslim, 11 pp less for SC, 7.9 pp less for OBC however 14.7 pp more for FC. This suggests the poor land valuation of the land owned by ST and OBC. The poor land valuation could be due to poor land fertility in rural areas or less developed land area in urban areas. After highlighting the basic Representational Inequality (RI) at caste group level, I move to present the concentration of total wealth in the population- at all-India level, rural and urban area separately.

5.1 Concentration of Total Wealth

According to New World Wealth Report, in India, the cumulated wealth of all High Net Worth Individuals (HNWI) increased from \$ 310 billion to \$588 billion and their numbers increased from 84k in 2008 to 153.4k in 2012.²⁹ HNWI's are individuals owning net assets of more than \$1million (=Rs 60,000,00) value. Correspondingly, in the same time period, as per Reserve Bank of India report, the decrease in the population of BPL (Below Poverty Line; Monthly consumption below Rs.1000) was from 407k to 269k. The rate of increase in HNWI's was 82% compared to reduction rate of BPL population by 24%.

This section deals with estimating the top share of wealth historically using surveys and millionaires list.³⁰ First I use micro-data from the NSS AIDIS surveys (for the years 1991, 2002 and 2012) and tabulated data from NSS AIDIS annual reports (for the years 1961,1971 and 1981) to estimate the top share. The tabulated data provides certain brackets of wealth with total population and total wealth in that bracket. I use non-parametric Generalized Pareto Interpolation method to generate a continuous distribution of wealth from the limited information in the wealth intervals (containing average and number of individuals falling into that bracket). Micro-data from the surveys in itself provide the full distribution. However, I test Generalized Pareto Interpolation programme by estimating the full distribution from it and comparing with the survey distribution for 1991-2012 surveys. The difference in decile level shares from generalized percentiles method and survey shares is positive in lower deciles and negative in top decile.³¹ This provides a robustness check that the estimates of the top decile share are conservative and is not overestimated. At the end the results presented here are from generalized percentile method to compare across years, to limit the bias due to different methods.

5.1.1 Two Contrasting Ends

In this section comparison is drawn between the top and the bottom percentile population to show the contrasting nature of wealth inequality. At all-India level, top 10% of population had 45% of total wealth in 1981 which increased to ~ 58%, an increase of 15 percentage points (pp) in 30 years. There is a major jump in 2012 from 2002 almost 10pp. On the other hand looking at bottom 10% Fig. 2b we see, total wealth share is less than .6 % for all the years and for both sectors. Wealth inequality is lower in rural areas than in urban areas and we see an improving trend (i.e. increase in wealth share of Bottom 10%) in both rural and urban areas.

The existence of micro-data from NSS-AIDIS survey from 1991 onwards help in robustness check with different combinations like gross individual wealth equally split in all the household members, net individual wealth equally split in adult members of households and net individual wealth equally split among all the household members. The variations are not very far from the numbers presented in the main text (which is gross individual wealth split at individual level). In the discussion section later, I explain the differences from different variations.

Rural: Looking into rural sector top decile share see a slight decrease/stagnation in the period of 1961-1981 at ~ 43%, which gets withered away in later decades when the top decile share jumped to 51.2%. In 60 years, the change in top decile share is of +8 pp.

Urban: The top decile share in total wealth stood at 55% in 1991 which first declined to 52.5% in 2002 and then gained 7pp to reach to 60% level. In 1991-2002 the top 10% wealth share decreases only in Urban areas while it remains constant in Rural areas. Nevertheless after 2002 the 10% wealth share increases faster in urban areas than in rural areas.

²⁸Though the Act is not only restricted to ST, the condition that last 4 generation should have operated the forest land will automatically remove all other caste groups.

²⁹In 2018 the numbers of HNWI's stands at 3,30,400

³⁰I am pursuing to understand the methodology of HNWI's list of Capgemini and if possible using their dataset to overcome the limitation of few individuals in Forbes dataset.

³¹The reduction in top decile share is 1.76 pp ,1.7 pp and 2.6 pp in 1991, 2002 and 2012 respectively using generalized percentile programme.

Figure 2: Wealth Share:Top 10% and Bottom 10%

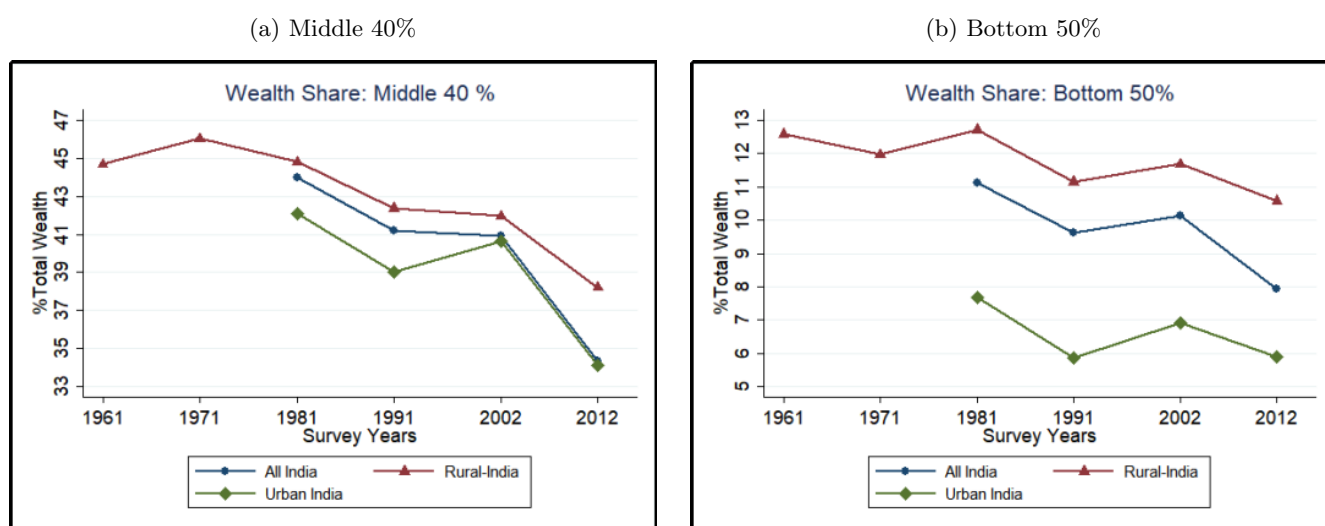

Note: Author's calculation using NSS-AIDIS datasets and reports. Rural India series is from 1961. Urban India series information is available only from 1981.

5.1.2 Weak Base

The share of Middle 40% (which is defined as population in 6th-9th deciles) and Bottom 50% (1st-5th deciles) of the population, can be seen in Fig. 3a and Fig 3b respectively. We see that middle wealth population in Rural India used to own 45% total value of rural wealth in 1961 which has decreased to ~ 39% in 2012. The wealth share almost equals the population share of the middle 40%. In Urban sector, Middle 40% share has declined to below 35% in 2012 from ~ 42% in 1981. We see a jump in 2002 in Middle wealth population which is in contrast to the decline of Top 10% share we saw above. At all-India level, the share of middle wealth population is now closer to urban sector level at ~ 35%. The share of bottom 50% (Fig. 3b) in Rural India has decreased from 12.6% in 1961 to 10.5% in 2012 which implies a drop of 15.9%. Inequality in Urban regions is more extreme. In those regions the bottom 50% owns only 5.9% of total wealth. At all-India level the share of this section stands at 8%. The condition of half of the population of country is dismal in the share of total wealth.

Figure 3: Wealth Share:Middle 40% and Bottom 50%

5.1.3 Rich Topping

The inequality within top decile is visible from the graphs Fig. 4a and 4b. Wealth is heavily concentrated at the top. *Rural*: Out of the total asset share with top decile in Rural area, top 5% population owned 70.4% in 1961 and 74.3% in 2012. Looking at the evolution of portion of top 1% population in total wealth share of top 10% population, we see first a decrease from 1961 to 1981 and then an increase post 1981 to reach at 33.5% ($=17.14 \times 100 / 51.2$). The period of 1961-71 and 1971-81 saw a small decline which happen to be the years when land reforms were implemented in

India. Land Ceiling Act implementation in 1960's might have some role to play. Under Land Ceiling act, different ceilings on the area of land ownership was specified in different states and land above the ceiling was confiscated by the government to distribute among poor farmers. The small decline gets nullified by a jump in 1991, followed by a decade of stagnation and in the last decade increasing to its highest level.

Urban: The concentration at top is higher in Urban area than in rural area. The portion of wealth share of Top 5% population in the wealth share of top decile, increased from 71% in 1981 to 78% in 2012. Similarly Top 1% population captured 29.4% in 1981 to 44.5% in 2012 of the total wealth share of top decile. The year of 2002 is an aberration, when wealth share of top 5% and top 1% (and also of top 10% share) saw a major decline in urban area. This is the time period just after the implementation of liberalization in India. The decrease in the wealth share at Top 10% is distributed across all the lower deciles. All other 9 deciles saw an increase in their wealth share. Rural area seems to be un-affected in this period in terms of wealth distribution.

All-India: Since the proportion of rural wealth in total wealth saw a decline from 68.5% in 1981 to 45.1% in 2012, we see the top share curve is now more closer to Urban area. The concentration at Top 5% and Top 1% shows a similar trend as in Urban area.

Figure 4: Wealth Share:Top 5% and Top 1%

It has been well documented by Subramanian and Jayraj (2006) that top wealth is not captured properly in the dataset. One can easily see this from the maximum wealth captured in the dataset. The ratio of maximum wealth in the Forbes list to the maximum wealth in survey is 3250, 16507 and 3279 in 1991, 2002 and 2012 respectively.³² We see that the ratio is very high for the year 2002, compared to 1991 and 2012. The total wealth from the Forbes list comes from only 1, 5 and 46 individuals in 1991, 2002 and 2012 respectively owning 0.17%, 1.72% and 2.65% of the total survey wealth in the same order. There is indeed the issue of under-representation in the survey. Hence to overcome this issue, I use Forbes millionaires list to correct the top share for 2012 and 2002.³³

Top shares post correction I:

There are several variants to correct the top shares using some external source such as Forbes list. One simple method is adding these few individuals in the dataset. This will certainly change the distribution to some extent, but the biggest demerit is that this method ignores all individuals between the poorest individual in the Forbes list and the richest individual in the survey. Put differently, there is no way to know the corresponding weights on the rich individuals. Hence I refrain from using this technique.

The second method, which I use here, is based on the assumption that wealth distribution follows Pareto distribution at top end of the distribution (Blanchet 2016). This approach doesn't tell exactly the threshold above which the distribution will be a good approximation. Hence I check with range of thresholds ($p=95$ means I replace top 5% survey distribution with Pareto generated distribution) to estimate the evolution of top shares.

Forbes millionaires list provides a list of very few individuals (5 in 2002; 46 in 2012) but can be used to generate the distribution utilizing the convenient property of Pareto distribution that the curve of $\log(\text{wealth})$ and $\log(\text{rank})$ follows straight line. I simulate the wealth using millionaire's list till the threshold (p) and replace the top wealth

³²The historical exchange rate is taken from Foreign Exchange Dealers' Association of India. Exchange rate conversion from \$ to Rs: 1991- 24.5, 2002- 48.4 and 2012- 54.4. The Forbes wealth is assumed to be at individual level, however some of the names in the Forbes list is mentioned as Birla family. Unfortunately the household size is not present in Forbes data. The potential concern is that if the wealth is truly at household level, the discrepancy between Forbes and survey will be inflated.

³³For the year 1991, there is only 1 individual present in the Forbes list. For prior years, I intend to use the data of top 0.1% wealth holder from estate tax returns, which is still under preparation (Kumar, 2016)

distribution from the survey with this synthetic Pareto distribution. The top share post this correction is present in the Table 8.³⁴

The below table (Table 8) shows a stable increase in the top share as we replace more and more top population by Pareto tail. It hints toward higher p value to be more apt for the replacement with pareto curve. Hence my quoted top wealth share would be the bottom row, where I replace top 0.1% of the population to be replaced by the Pareto curve generated from Forbes millionaires list. We can see the top decile share increased by 7pp to reach 55% for 2002 and 4 pp for to reach 62% for 2012 . The increase is higher in 2002 is not surprising as we saw above that the ratio of maximum wealth in the Forbes list to the maximum wealth in survey was higher in 2002 than in 2012, suggesting that 2002 did worse in capturing the wealthy individuals.

Table 8: Top Wealth Share

	Top Wealth Share												
	2002						2012						
Raw Survey Shares	10%	5%	1%	0.10%	0.01%	0.001%	10%	5%	1%	0.10%	0.01%	0.001%	
	48.94	34.86	14.46	3.72	0.86		57.7	44.4	23.2	10.06	5.24		
	Post Correction Shares												
Threshold p for Pareto	90	66.19	56.39	38.79	22.56	12.95	7.24	68.9	58.88	40.8	23.98	13.91	7.88
	91	66.15	56.35	38.78	22.56	12.95	7.25	69.1	59.02	40.85	23.97	13.88	7.84
	92	65.92	56.16	38.69	22.55	12.97	7.27	69.15	59.06	40.86	23.96	13.87	7.84
	93	65.72	55.98	38.61	22.54	12.98	7.29	69.1	59.01	40.84	23.96	13.88	7.84
	94	65.39	55.62	38.44	22.5	13.00	7.32	69	58.9	40.8	23.96	13.89	7.87

	96	64.29	54.26	37.72	22.3	13	7.38	68.74	58.56	40.62	23.92	13.9	7.89
	97	63.53	53.29	37.08	22.09	12.97	7.43	68.15	57.8	40.15	23.83	13.95	7.97
	97.5	63.02	52.63	36.57	21.91	12.93	7.44	67.8	57.33	39.79	23.73	13.95	8.01
	98	62.32	51.74	35.79	21.61	12.86	7.45	67.25	56.6	39.14	23.53	13.94	8.05
	98.5	61.5	50.69	34.71	21.18	12.73	7.44	66.64	55.8	38.33	23.26	13.91	8.11
	99	60.2	49.03	32.71	20.33	12.44	7.39	66.03	54.99	37.29	22.88	13.83	8.15
	99.5	58.13	46.38	29.21	18.5	11.71	7.19	64.53	53	34.54	21.62	13.47	8.16
	99.9	54.96	42.31	23.85	13.94	9.6	6.39	62.12	49.81	30.07	17.81	12.02	7.86

It is important here to emphasize that there are some limitations in the methodologies, however comparison with other literature show that the results are quite close. There are some data limitations while using surveys or even Forbes- like under-reporting, non-covering etc. Lack of wealth price index is a big issue in comparing the evolution of per-capita wealth in the country.

Robustness Check : I repeat the correction process using the Business Standard rich list produced by Business Standard magazine.³⁵ The wealth present is net wealth and some of the wealth is at family level. I assume an adult family size of five and equally split the wealth among all the adult family members. The top share is provided below.

Table 9: Top Wealth Share (Using Business Standard list)

	Top Wealth Share (Net Wealth)												
	2002						2012						
Raw Survey Shares	10%	5%	1%	0.10%	0.01%	0.001%	10%	5%	1%	0.10%	0.01%	0.001%	
	49.48	35.31	14.69	3.77	0.89		58.33	45	23.73	10.37	5.46

	99.9	55.21	42.44	23.71	13.53	9.12	5.94	62.51	50.1	30.19	17.75	11.66	7.51

³⁴I also check the top share with the Net wealth instead of Gross wealth and using Household size. The results are provided in the appendix 23.

³⁵I would like to thanks Professor Sitabhra Sinha (Institute of Mathematical Sciences, Chennai) for providing me the list.

Top shares post correction II: Experiment: I present this correction method which is an alternative way and do not require assumption of Pareto distribution. The basic idea is to correct the land value in the survey dataset using the market land price from the website portals which facilitates seller to advertise his/her plot of land/apartments and prospective buyers can search for these posted advertisements.³⁶ I use one of the websites to create a dataset of cities and associated land prices (per area)³⁷. I then use housing price index from National Housing Bank to convert the prices from website to 2012 level. I use this deflated land rates to correct the land values in NSS AIDIS survey dataset for the year 2012, using the land owned area. Rest all the asset values are kept untouched. The share of Top 10% share increases to 80% which is not very far from wealth share of top decile (73%) in USA in 2014. My calculations are upward biased due to several reasons- first I correct only for 30 cities out of 42 cities available in the NSS AIDIS datasets (for which housing price index was available). These big 30 cities covers all the metropolitan cities like Delhi, Mumbai, Kolkata etc. which have probably the most expensive land rates in India. Second, the land rates gathered from the websites is not representative for the whole city due to two reasons. I use only one website where only some of the sellers post their advertisement. Second I only take five land rates per cities and took average to get the land rate of the whole city. A proper analysis will require using multiple websites and more samples of land rates which I intend to do in future research.

5.2 Representation of Different Castes by Decile

After establishing general findings on wealth inequality, this subsection explores if there is any particular social group which is benefited more by this inequality. If the economic inequality is independent of social inequality one will expect the probability of falling into different wealth deciles/percentiles to be same for any social group. Any digression from this hints towards interaction of social and economic inequality. I use the term representational inequality (RI) from Jayadev and Reddy (2011) symbolizing segregation among social groups in a given attribute space (which here is wealth). The basic idea is to compare the population share of a given caste group in a given wealth decile with its share in overall population. So for example if OBC population is 45% of the overall population, a perfectly representational equality will imply representation of 45% OBC population in all the deciles. Any deviation from this will lead to Representational Inequality. The statistics I estimate to compare can be given by:

$$RI_j^{YCD} = \frac{Popshare_j^{YCD} - Popshare_j^{YC}}{Popshare_j^{YC}} \quad (1)$$

where $Popshare_j^{YCD}$ denote the population share of caste C in decile D in year Y for sector $j \in (Rural, Urban, India)$. A higher representation (than the population share) for a caste group in top decile, will increase representational inequality. That caste group is the beneficiary of the inequality. On the other hand higher representation (than the population share) of a caste group in the bottom deciles also increase RI, but that caste group is in a way victim of the inequality.

The RI statistics are present in the Table 10 for three categories- Top 10%, Middle 40% and Bottom 50%. A positive value imply more than the proportionate population share. Looking at the top decile in both Rural and Urban sector, we see that only FC³⁸ have positive RI or in a sense beneficiary of the inequality. All other social groups SC/ST/OBC and Muslims have negative RI, which means they are under-represented in top decile. Looking at Middle 40%, we can see that ST, SC and Muslims have negative RI in both 2002 and 2012. Again only FC has positive RI. In Bottom 50%, only FC has considerable negative value of RI, OBC is close to zero. SC and ST have quite high value. The RI pattern is similar in Rural and Urban area.

³⁶In recent years many of such websites have sprung in India like 99acres.com, magicbricks.com etc.

³⁷I randomly pick 5 land rates from the website per city and took mean of it. This sample is nowhere representative. This is just an experiment to present the method

³⁸Apart from Other which is a small rich minority group

Table 10: Representational Inequality

	Others	-0.5	0.11	2.11	-0.46	0.07	2.17

Source: Author's calculation. The numbers are comparable across caste and years as they are standardised. A positive value implies more population share in that class group than their population share in overall population.

In summary, we observe that that FC is relatively more present in top 10% and Middle 40% of population where almost 90% of the wealth is concentrated. SC, ST and Muslims have relatively more presence in the Bottom 50%. OBC population is evenly distributed across wealth deciles. The representational inequality is silent on the relative wealth share. It only captures the representation of caste groups in a pre-decided bins, which here is chosen as deciles. Next, I analyse the wealth share under Rural and Urban separately.

5.2.1 Rural

Fig 5a and 5b show the percentage share of different castes in different deciles in Rural areas. For the 2002-03 survey, in the top decile 40% belong to FC and 40% belong to OBC. The representation of OBC in top decile is slightly less than than their population share in the survey (which is 41.97%), however FC is almost double represented in top decile (21.27% population share). While in 2012, we see a slight drop in the representation of FC(to 32%) and a corresponding increase in OBC(45.9%) in the top decile. Not to miss the fact that their population share of OBC and FC changed to 44.2% and 17.6%. Hence relative to their total population share, the share of FC represented in the top decile remains almost constant while OBC share improved slightly. The combined share of FC and OBC in the top decile has almost remained same in a decade (79.43% in 2002-03 and 78.14% in 2012-13). The representation of SC, ST and Muslim is lower in the top 10% (in fact in all top 5 deciles, their representation is lower) than their population share. The situation is the worst for SC. Their representation in Top 50% is almost 41 percentage points (pp) lower than their population share in 2002.³⁹ The representation of ST and Muslim in Top 50% is lower by 15.5 pp and 9 pp respectively than their population share in 2002. in 2012 SC are under-represented by 20.4 pp, ST by 29 pp and Muslims by 5pp in the top 50%. This implies a deterioration of the relative wealth of ST.

³⁹So correspondingly they are over-represented in Bottom 50% by 41 pp.

Figure 5: Proportion of different castes-Rural

Note: This graph shows the proportion of population in different gross wealth deciles using NSS AIDIS datasets in Rural area.x axis is wealth deciles, yaxis is population share. "Other" population is not presented here as their population share is very small.

5.2.2 Urban

The results in urban areas are very different from the results on rural areas, just discussed. Fig 6a and 6b show the percentage share of different castes in different deciles in Urban areas. For 2002-2003 survey, in the Top 10% population, 58% are from FC and 23% are from OBC. The representation of OBC in top decile is 12.4 pp less and for FC is 25 pp more than their respective population share in the survey. In 2012-13 the increase in OBC representation to 29% and decrease in FC representation to 54.7% is in line with their population change. The combined share of FC and OBC increased from 81.3% in 2002-03 to 84% in 2012-13, while their combined population saw an increase from 68.6% o 71.9%. SC, ST and Muslim share in top decile are not only below their total population share in top decile but also lower in combined five top deciles. Similar to rural areas SC is skewed in the lower tail of the wealth distribution. Its representation in Top 50% is 27.7 percentage points (pp) lower than its population share in 2002. The under-representation of ST and Muslims in the top 50% is 5pp and 13pp respectively in 2002. In 2012-13 the representation for SC, ST and Muslim in 2012 lies below their population share by 24.2 pp, 4.8 pp and 9 pp respectively i.e. an improvement in SC and Muslim.

Figure 6: Proportion of different castes-Urban

Note: This graph shows the proportion of population in different gross wealth deciles in Urban area.x axis is wealth deciles, y axis is population share. "Other" population is not presented here as the population share is very small.

5.2.3 Discussion

Some important takeaways from the above observations are:

First SC has the lowest wealth ownership in urban and rural areas. There has been some improvement over a decade but the condition is far from satisfactory. Second, FC is still overly represented in Top 10% or Top 50% of the population. Third I want to highlight the issue of **reclassification of castes**. We observed an increase in the relative representation (RI- changed from -0.21 to -0.17) of OBC population in Top 10% from 2002 to 2012 time period. If the population share of OBC in overall population had remained same in the two time periods and there was no scope of inclusion or exclusion in OBC, then this result would have suggested an improvement in OBC caste group. However, OBC group of caste is a floating list of castes. Mandal Commission in 1980 charted out the criteria based on which OBC status is conferred to a caste for receiving the reservation benefits.⁴⁰ National Council of Backward Commission (NCBC)- a statutory body, hears the petition from different castes for the request of inclusion into the OBC list. Time and again different castes have been included in the list while there has been no exclusion of the castes from the list in last 17 years (Annual Reports of NCBC). This is probably one of the main reasons behind the increase in the population share of OBC. Fig. 7 depicts the change in the population share of OBC in different deciles. We see a positive change in the population share for OBC across all the deciles. Correspondingly there is decline in population share of FC, with major declines towards higher deciles. There is also a decline in Muslim population which is concentrated more in lower deciles than in higher deciles. This further raises another concern whether relatively rich FC castes are being included into OBC category.

Figure 7: Change in population share between 2002 and 2012

Note: Author’s calculation from NSS AIDIS surveys. It represents that OBC population has seen a positive change in population vis-a-vis drop in population share in FC and Muslim groups. y axis denotes the change in population share in time period 2002-2012.

There could be other possibilities of increase in OBC population like -increase in population share is due to sampling issues, higher growth rate of OBC, higher Inter caste marriage into OBC, classification of other communities (like SC/ST) into OBC.

5.3 Total Wealth Inequality within Caste

Till now, I have treated the broad social groups/castes SC, ST, OBC, FC and Muslims as one homogeneous groups- because government affirmative actions does so. However, this is far from social reality. Each one of them is composed of hundreds of different narrower version of castes (jatis) in hierarchical fashion. This multifarious layering could create heterogeneity on economic aspects. Several other reasons like- accessibility to education, different level of awareness and ability - can create heterogeneity. In this section, I try to analyse the distribution of wealth within every caste. In a big country like India, even if groups are small, this wouldn’t be a reason not to study them. Further looking at inequality only across castes gives an impression of economic uniformity within the castes, which will be put into question in this section.

⁴⁰A score is calculated based on social, educational and economic criteria. Castes which score above a fixed point gets OBC status. Higher weight is assigned to social criteria. This ensure socially backward castes have higher chance of getting the status.

5.3.1 Top Deciles

Fig. 8a, 8b and 8c show the share of wealth with Top 10%, Top 5% and Top 1% respectively. We can see an increasing trend of within caste inequality in all the castes. The divide between FC and rest of the caste is more prominent in 2012 than before. Interestingly within ST the allocation of wealth to Top 1%, Top 5% and Top 10% population increased than that of in SC in 2012 which was opposite three decades earlier.

Within *Forward Caste*, Top 1% within FC owned almost 13.6% of the total FC wealth in 2002 which increased to 29.4% in 2012. Top 5% owned 32% in 2002 which increased to 47.6% in 2012. And Top 10% now owns 60% of the total FC wealth. This is a drastic change in ten years is which needs more enquiry. The inequality within FC group is the highest.

Within *ST*, Top 1% owned 10.7% of total ST wealth in 1991, which increased to 15.1% in 2002 and further to above 19.5% in 2012. Top 5% share of total ST wealth increased from 27.7% in 1991 to 38.93% in 2012. Top 10% of share increased from 40.3% in 1991 to 51.4% in 2012. This caste group has seen a consistent rise in within caste inequality. Within *SC*, Top 1% owned 11.9% of total SS wealth in 1991, which decreased to 10.83% in 2002 and then increased to 14.4% in 2012. Top 5% share of total SC wealth increased from 30.3% in 1991 to 33.5% in 2012. Top 10% of SC share increased from 43.6% in 1991 to 46.7% in 2012. SC has the lowest level of within caste inequality in terms of top decile share.

Within *OBC*, Top 10% share increased from 46.2% in 2002 to 52% in 2012.

Figure 8: Share of Top Deciles Within Caste

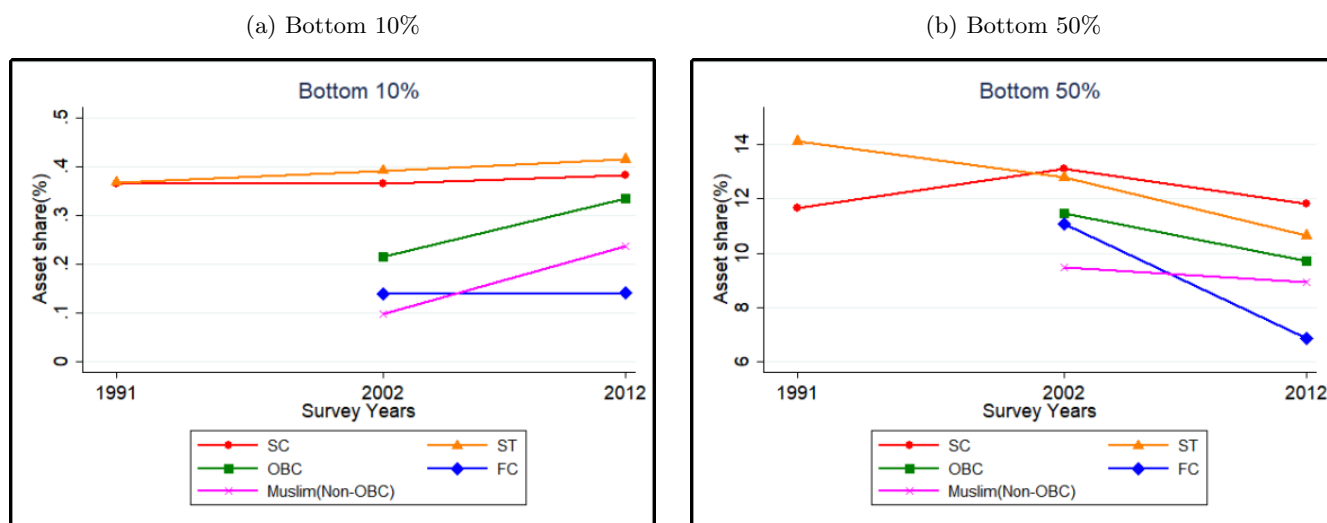

Source: Author's calculation using NSS AIDIS dataset. This graph shows the wealth share in Top 10%,5% and 1% within different different caste groups.

5.3.2 Lower Deciles

Fig 9b shows that Bottom 50% of the population has lost 2-4 pp within all the caste categories. The major decline of their share in FC followed by ST, OBC and SC and Muslims. Fig 9a shows that there is slight improvement of wealth share in Bottom 10% population within every caste. The gain is highest in Muslims (.14 pp) followed by OBC(.12 pp).

Figure 9: Share of Lower Deciles Within Caste

Source: Author's calculation using NSS AIDIS dataset. This graph shows the wealth share in lower deciles within different different caste groups.

Inequality is quite high in every caste group. The threshold wealth by decile and caste is provided in the Table 22. One way to intuitively visualise these numbers is to look at how many times of wealth an individual needs to enter into 10th decile than to enter into 2nd decile in given wealth distribution within every caste group (i.e. ratio of threshold of 10th decile and threshold of 2nd decile). In 2002, a person from ST group needed 23(=118,060/5625) times more wealth to reach to top decile from the threshold of second decile. Similarly for SC, OBC, FC and Muslim one required 22,32,45 and 57 times respectively to enter into 10th decile.

5.3.3 Discussion

We see a very high within caste inequality which has increased from 2002-2012. It hints that treating these big administrative castes as homogeneous groups is far from reality. Looking at the entire distribution, all the population from 2nd to 9th have lost their share within castes. The major gain is in the top decile and a minor gain in the bottom decile within every caste. The inequality within FC has increased and it is potentially one of the reasons behind uneasiness among certain Forward caste groups in country and their demand for OBC status- which helps them to gain access into reservation benefits (positive affirmation). "Jat" an agrarian community from North India, are demanding the OBC status in Central Government list of OBC^{41, 42}. Patidar (people with well known surnames Patel) group in 2015, started agitation for similar demand which became the central issue in 2017 state's election.⁴³. These caste groups are not considered socially backward and highly likely to have better economic outcomes. The surprising demand for OBC from these communities can be rationalized through the close threshold ownership and a sense of competition for scarce resources. From Table 22 we see close threshold values of FC 8th and 9th decile and OBC 10th decile. Lets call these two groups A and B. The population share group A and group B is almost same ($A=2*.1*20\%$; $B=.1*40$). There are two differences between A and B. Group A is considered upper caste in the society and hence may have some advantage in terms of better connections to get into jobs. Group B has reservation benefits in government jobs. If the utility from being in upper caste reduces due to any reason than and the perceived utility from being in OBC group increases group A will demand for OBC status. Since in reality there are many castes in group A with different hierarchy, if not whole group A, some castes from A will sure demand for OBC status. The perceived benefits come from expectation of lesser competition in OBC. The demand for OBC status can lead to reclassification which is probably one of the reason for the increase in OBC population. The unmet demand might die down or might resurge again with change in the government. This is what I call Forward caste backlash can be seen in different forms in the society today.

There is a large literature finding that people evaluate their life relative to individuals that are similar to them. For example, Luttmer (2004) finds that subjective well being reports depends on whether a respondent earns well relative to her neighbors. He uses US data. Furthermore, using data from former soviet countries,(Senik, 2009) finds that colleagues and former schoolmates are very important for relative income comparison. Lets assume that the same

⁴¹There are two different lists- Central level OBC list, which makes a caste eligible for reservation benefits in central universities and central government jobs and a corresponding state level OBC list.

⁴²https://en.wikipedia.org/wiki/Jat_reservation_agitation

⁴³https://en.wikipedia.org/wiki/Patidar_reservation_agitation

mechanism holds in India. Then, if income and wealth are correlated, people with similar wealth might work together or go to the same schools. Thus FC individuals from the 8th decile of the FC wealth distribution might work together with OBC individuals from their respective 10th decile. In this case FC individuals might feel deprived, when their OBC colleagues with similar wealth level get a prestigious position in administration due to reservations. Maybe they just don't consider members of the FC tenth decile as a relevant reference group.

5.4 Total Land Inequality

Land forms the major part of asset value and contribution of land in total wealth has almost remained at same level in last 60 years. In this section I analyse inequality coming from unequal distribution of land ownership. NSS AIDIS provides information on land area owned and its valuation⁴⁴. We first look at the landless population in the data. Landlessness in India has increased from 15% to 24% (Fig 16). The landlessness in rural area (< 14%) is much lower than landlessness in urban area (45%). In Figure 10 I plot the percentage of population with no land by caste groups in rural and urban sector separately. The landlessness among SC increased by 10 pp in 1991-2002. Similarly ST saw a rise in landlessness in this decade by 3 pp. In Urban areas the pattern is similar. I discuss the big increase in landlessness among SC and ST in the period from 1991 to 2002 in detail below. One of the main tools used in liberalization process was de-licensing. Before 1990, India was almost a closed economy. Setting up an industry required license from the government and the allocation of land to the industries was decided while giving licenses. Post liberalization companies are free to choose their location and will obviously try to target the land which can be easily acquired at cheaper prices (Sardana, 2012). Since ST and SC are vulnerable to shocks and relatively more poor their bargaining position might be bad. This can explain selling of land at low prices. A second reason for the post 1991 increase in landlessness is industrialisation. Economic progress of certainly will involve diversion of agricultural or relatively unproductive/unused land towards construction of roads, rails, industries etc. This will in general increase landlessness. But we see higher rate of landlessness in SC community than in any other communities. The reason might be that the land was acquired without proper compensation. ST community is more attached to forest areas where acquiring land is more tedious due to complex regulations related to environment and restrictions on buying land managed under Scheduled Tribe area by outsiders. This might be the reasons for reduced rate of landlessness among ST.

Among other communities, FC has the lowest level of landlessness in both Rural and Urban area. We see a drop in landlessness across all castes in 2012 from 2002. The drop can be due to the fact that land area was captured till 3 decimal points in 2012 but only till 2 decimal points in 2002.⁴⁵

Figure 10: Share of Population - Decilewise

5.4.1 Concentration of Land Within Land-Owning Population

I restrict the analysis of concentration of land area and land value among the population with non-zero land area. I perform deciles level analysis, with both land area based deciles and land value based deciles. Both have their own advantages. Land value based deciles are more intuitive as individuals with more land value will be categorized into higher deciles. However, the reasons for the change in land value share from one year to another can be due to multiple reasons like- appreciation/depreciation of the existing land (without any change in land area), buying/selling of land

⁴⁴One should keep in mind that land valuation was different in 2002 and 2012

⁴⁵Though for the analysis to be comparable I have rounded of the land area to two digits, it will not correct the behavioural differences in answering the question by respondents. More people will report non-zero land area, thereby reducing the landlessness.

or due to the change in the method of collecting information. It is difficult to narrow down to one reason or interaction of all the factors. I intend to explore more in my future research. Land area based deciles, on the other hand will classify large land owners in terms of area into higher deciles. A forest dweller with large land area will be categorized into top decile.

Deciles based on Land Area: Table 11 shows the top 10% of population based on Land Area in Rural area occupied 48.4% land area in 1991 which increased slightly to 49.4% in 2012. The corresponding land value of this share of land was 33.9% in 1991 and increased to 38.2% in 2012, i.e. an increase of 4.7 pp. The change in land valuation could be due to either increase in the valuation of the existing land or purchase of the more valued land. Unfortunately I can't elaborate more on this further because of lack of necessary information in the survey datasets. In Urban area, the top 10% of the population occupy 83.1% of the total land area in 1991 which decreased to 77% in 2012. However, the land value share (i.e. for the land owned by top 10% population) increased from 27.4% to 34.3%.

The entire distribution of land area in Rural sector seems quite stable. The bottom 50% population share of land area has remained almost constant at 6.8% in Rural area. The value increased from 15% in 1991 to 17.9% in 2012. For Middle 40% (i.e. 6th-9th decile population) the share remained constant at 44% with land value decreasing from 51% in 1991 to 44% in 2012. Urban area is more dynamic. Bottom 50% doubled their land share from .9% to 1.8% in 2002 but saw a decline in next decade to reach 1.4% land of total land area. The land value increased too from 27.5% in 1991 to 30.8% in 2002, however declined to 23% in 2012. Middle 40% occupied 16% of land in 1991 which decreased to 11% in 2002, then increased to 21% in 2012. The land value follows similar trend which first decreased from 45.1% in 1991 to 39% in 2002 and then increased to 42.7% in 2012.

Table 11: Land Area and its Value distribution

Percentage of Land Area Ownership									
	Bottom 50 %			Middle 40%			Top 10%		
Year	1991	2002	2012	1991	2002	2012	1991	2002	2012

Rural	6.68	6.76	6.79	44.98	44.47	43.78	48.34	48.76	49.43
Urban	0.86	1.77	1.36	16.05	11.27	20.96	83.09	86.96	77.68
Percentage of Land Value Ownership									
	Bottom 50%			Middle 40%			Top 10%		
Year	1991	2002	2012	1991	2002	2012	1991	2002	2012
India	21.67	24.80	28.83	43.72	42.99	41.67	32.50	33.88	35.30
Rural	15.01	15.92	17.85	51.12	48.47	44.00	33.87	35.61	38.14
Urban	27.53	30.80	23.02	45.13	39.39	42.66	27.35	29.81	34.32

Source: Author's calculation using NSS AIDIS datasets. Design weights are used to estimate these values. The deciles are based on land area.

Decile based on Land Value: The top 10% of the population based on land value, owned 53% in 1991 which increased to 61.5% in 2012. The figures are quite close to the concentration of total wealth share we saw before. The corresponding share of land area at all-India level has decreased from 31.6% in 1991 to 29.1% in 2012. For the middle 40% classes the land value varies more than the land area. The land value has decreased $\sim 5 - 6$ pp in both Rural and Urban area. Moreover there is a decline of ~ 2 pp in the Bottom 50% of the population. Even though this decline is smaller than the decline in Middle 40%, the base is also very small, hence the percentage change is higher.

Table 12: Land Value and its Area distribution

Percentage of Land Area Ownership									
	Bottom 50 %			Middle 40%			Top 10%		
Year	1991	2002	2012	1991	2002	2012	1991	2002	2012

5.4.2 Discussion

The above analysis is only among the population with strictly positive land owned. Within those population, we saw that land area is highly concentrated in Urban areas to the top 10% population. However, big land doesn't mean valuable land too. In urban areas, usually the land in city center/City Business District (CBD) is very costly and in the fringes of city land is cheaper. That's why we see that 77% land owned by top decile by area (Table 11) in urban areas is only 34% of the total land value and a meagre 1.36% land area with Bottom 50% has 23% total land value in 2012. In rural area the gap is not so high as most of the land has been already been brought into agriculture. The thrust of agricultural revolution since 1960's may have to certain extent levelled out the variability of utility of the land in rural area.

6 Conclusion

Caste still plays important role in Indian society. The repercussions of past injustice towards lower castes are now becoming more visible with more information coming out in public. Economic outcomes do not see a converging trend. The relative growth of lower castes is either stable or declining. Probably the most worrying aspect for any Indian policy-makers is poor educational outcomes for lower caste population. This means that in coming future the condition will not improve either. The privatization of education is increasing the cost of education and the requirement of skills in employment is ever increasing. This research work has put together multiple nationally represented datasets to highlight some of the important issues of Indian form of inequality which has its origin in social structure of caste. Economic inequality is working as a skin for caste inequality. The ordering of averages based on any economic or educational parameters of different castes follow the caste hierarchy. The measures of positive discrimination is not working on average. There are some gains as the level of wealth and consumption inequality within lower castes has increased.

7.3 A.3 Methodologies

7.3.1 Stratification in NSS AIDIS

A two stage-stratified sample design with villages and urban blocks as First stage units (FSU) and households as Second-stage units (SSU) is adopted. The list of villages are drawn from the recent most available census information. Since 1971-72 there was an increase in the size of sample to get the estimates not only at all-India and individual states but also at broader regions within the states. The rural/urban area was divided into agricultural regions⁴⁶ having similar crop patterns and population density. Each region was further divided into strata by grouping geographically contiguous tehsils/districts having similar characteristics based on altitude, transport and communication facilities. The effort was to keep the population dependent on agriculture same across all strata⁴⁷. Each stratum was grouped into two independent sub-samples of 12 villages each⁴⁸, on the basis of circular systematically with equal probability. All the households in sample villages were divided into 4 sub-strata (non-cultivators, small, medium and large classes of cultivator) on the basis of land area operated. The non-cultivator sub-stratum was further divided into agricultural labourers, artisans and other non-cultivators based on their means of livelihood. The cut-off points for small, medium and large cultivators was decided on regional basis to equalise the total land area operated in each of the sub-strata at regional level. From each sub-stratum in a village on average 3 households were selected linear systematically with specified intervals and random starts, which were pre-determined to design self-weighting at the regional level for each sub-stratum. The estimate of the state total Y for a given y_{sitj} value of characteristic, where j denotes household, t for sub-stratum, i for village and s- rural stratum is based on following formula:

$$Y = \sum_{t=1}^4 \sum_{s=1}^k M_{st} \sum_{i=1}^{n_s} \sum_{j=1}^{h_{sit}} Y_{sitj} \quad (2)$$

where M^{st} is the multiplier for a given stratum s and sub-stratum t. It varies from one sub-stratum to other but remains constant over the strata in a region. k is the number of rural strata in state, n_s is the number of sample villages from a given stratum s and h_{sit} is the number of sample household from a stratum s, substratum t and village i.

In 1991-92 the major change in sampling method was that land possession and indebtedness status both were used. The stratum within each agro-economic regions were decided based on the population. In rural areas, each region with district population less than 1.8 million⁴⁹ formed a single basic stratum. Larger districts were divided into two or more strata, by grouping contiguous tehsils to keep similar population density and crop pattern. In Urban areas each million population city formed a separate stratum by itself. The remaining towns of each region were grouped to form three different strata based on the population criteria - 200k-1 million 50k-200k and less than 50k. The selection of sample villages was done by Probability proportional to size with replacement (PPSWR) with population as the size of variable and the sample blocks were selected by simple random sampling without replacement. Both are in the form of two independent sub-samples.

⁴⁶66 in 1971-72, 78 in 1991

⁴⁷In 1971-72 there were 379 rural strata

⁴⁸except few smaller states, and if the stratum was very big it was divided into manageable investigation zones

⁴⁹1.5 million for Assam

In Rural sector 7 AIDIS sub-strata were formed based on - "land possession" and "indebtedness status" of the households.⁵⁰ Independently 1,1,1,2,1,1, and 2 households were selected circular systematically from 1-7 sub-strata respectively. In Urban sector 7 AIDIS sub-strata were formed based on "monthly per capita expenditure (MPCE)" and "indebtedness" of households.⁵¹ Independently 1,1,1,1,2,2, and 1 households were selected circular systematically from 1-7 sub-strata respectively. Selection of households in each sub-stratum was done by Simple Random sampling without replacement (SRSWOR).

2002-03: The stratification exercise was similar to previous round of survey with slight modifications. It became multi-stage design with First stage, Intermediate stage and Ultimate stage units. The intermediate stage of sampling was in case of large FSU's. Ultimate stage unit was households, which was called Second stage unit in previous rounds. Two special stratas were formed from all small villages (< 50 population) and big villages (> 15000 population) in a state. Then in the rest of the villages/urban blocks stratum were formed as in 1991-92. Instead of 1.8 million district population criteria for strata formation in rural sector 2 million (as per 1991 census) or 2.5 million (as per 2001 census) was used. Sub-strata formation was similar as in 1991-92, with a slight change in rural sector where the focus changed on deciding X and Y - from keeping the same land area to fixing of certain population percentage. X and Y were determined at state level to ensure that 40% of households possess land area less than X, 40% possess land area between X-Y and 20% possess land area greater than Y. In Urban sector, based on MPCE, 4 groups were formed (instead of 3 in 1991-92)- less than A, A-B, B-C, > C. The cut-off points A, B and C was decided at state level to ensure 30% households fall into first, second and third groups with 10% falling into fourth. The first two groups were further divided into indebted and non-indebted. The last two groups were merged and further sub-divided into institutional indebted, non-institutional indebted and non-indebted. 14 households were selected from each sample village/block.

7.3.2 Converting from Household Level to Individual Level

I use non-parametric approach to estimate the average adult size at HH Level (AVAH) for 1961-62,1971-72 and 1981-82 survey years from the next round of survey years.⁵² Essentially I am assuming the decadal rate of change of AVAH during 1991-92 and 2002-03 to be same to predict AVAH for 1981-82. The assumption might fail if there is a big change in demography which makes these two decades growth rate entirely different. Since demographic factors usually experience slow changes except in extreme cases, like some natural calamity or disease wiping out a big share of population, war, or strict government policy like One child Policy. India didn't experience such drastic measures to be considered as demographic shock. The wars between 1961-1981⁵³ were not on a large scale in terms of human capital. Forced sterilization during Emergency (1975-77) resulted in 8 millions extra sterilization (as per Shah Commission Third Report 19789:2007) which was 1.5% of the 1971 census population is a potential threat to the assumption as it can bring negative change in the adult population after 20 years, i.e. 1991-2001 decade. Since household surveys ask for people living in the house, a simple migration can also impact AVAH. Census provides total migrating population with respect to total population which stand at 30.8%,28.7%,29.4%,26.6% and 29.3% in 1961, 1971, 1981, 1991 and 2001 respectively. The decadal variation is not too large to produce concern. Keeping the above potential issues in mind, I proceed with the estimation of AVAH.

The objective is to re-calculate the HH level wealth to individual level wealth. First Step is to estimate AVAH from next round of micro-surveys files. The procedure I followed is:

- 1) Assuming same decadal rate at decile level, predict AVAH and Average HH size (AVH) for 1981. 2) Correct the predicted 1981 AVH and AVAH values using "correction factors". These correction factors are:
 - a) AVH: A factor to make the predicted population level equal to the representative population of Survey.
 - b) AVAH: A factor to make the predicted adult population share same as in census.^{54,55}
- 3) Use the predicted AVH and AVAH for 1981 and repeat 1) and 2) to predict for year 1971.
- 4) Repeat 3) to predict for 1961 level.

The second step involves generating full distribution using Generalized Pareto Interpolation (using gpinter)- first at

⁵⁰First, based on land possession 4 groups were formed, namely non-cultivators (≤ 0.005 acres), small ($0.005-X$), medium ($X-Y$) and large ($\geq Y$) cultivators with increasing land area. X and Y varied with state to ensure that in all the three cultivators group total land area remained same. The first two groups were sub-divided into "indebted" and "non-indebted" groups to form AIDIS sub-strata 1-4. Medium and Large cultivators were then merged and subdivided into 3 AIDIS sub-strata- "indebted to institutional agencies with or without being indebted to non-institutional agencies", "indebted to non-institutional agencies alone" and "non-indebted".

⁵¹Households were first grouped into 3 classes - less than x, x-y and greater than y. The cut-off x and y was decided at state level, based on NSS consumption survey to allocate 30%,60% and 10% of the urban population of the state. Similar to in rural sector this three group were divided into 7 AIDIS sub-strata based on indebtedness.

⁵²The parametric approach imply estimating the adult population per HH using regression analysis with potential dependent variables like -age, education, place of residence, caste etc. But it will require micro-data which is lacking in our case

⁵³1962 India-China war- resulted in 10,000(0.002% of total population) human loss; 1965 India-Pakistan war resulted in 3000 casualties; 1971-72 India Pakistan war - 4000 casualties.

⁵⁴The data for adult population share is taken from the website: <https://www.populationpyramid.net/india/>, I use the same adult share for Rural and Urban area. It will be better to use separate. Lack of good source has resulted in compromising here.

⁵⁵Different sampling of adults in Census and survey might be a threat. For 1981, I have comparison between survey sampling and census at household level, which I use here. For 1971 and 1961, I use census population, which means survey population was perfect to the census population

HH level and then applying the decile wise estimated AVAH to recalibrate the p values, bracket average, threshold values at individual level and re-running gpinter programme at individual level.

Using predicted AVH and AVAH 1981 level, the above process is repeated for 1971 level. And then using predicted 1971 level, 1961 level is predicted.

7.3.3 Sampling Methodology in Surveys

1) Systematic Sampling implies selecting a sample from a given population based on a skip pattern with a sampling interval. So for example, every k^{th} element from a sequential population data is selected with a sampling interval of $k=N/n$ where n - number of selected units, N - Population units. There can be two types of systematic sampling schemes. First Linear systematic sampling which is used when N/n is an integer and k samples of exactly n units in a systematic manner can be collected with probability $1/k$. However, if N/n is not an integer then it is a problem which leads to the second type of systematic sampling, called Circular systematic sampling scheme. In this case once n is fixed, the skip k is taken as the minimum integer of N/n . There is a possibility of N possible distinct samples instead of k and hence probability $1/N$. The advantages of using systematic sampling over random sampling is that ordering of the population ensures representativeness and even spread of sample. It can be more efficient than SRSWOR when the ordering is related to the characteristics of the variable of interest. One limitation is that it requires the complete list with proper ordering. A bad ordering may lead to inefficient sample.
